CONNECTIVE TISSUE

- The connective tissue (CT) is found everywhere in the body.
- ➤ It is the most abundant and widely-distributed tissue by its several types.

Structural elements of connective tissue:

it is made up of

- □ cells
- ☐ Extracellular matrix which in turn has 2 elements the
- > ground substance
- > CT fibers.

Common characteristics of CT:

- 1. Common origin: all types of connective tissues arise from the mesenchyme = (mesoderm)
- 2. Several types of cells: they are widely-separated and immersed in an abundant intercellular substance (extracellular matrix) formed by these cells.
- 3. Extracellular matrix: where as all other tissues are composed mainly of cells, connective tissue is formed of abundant non-living extracellular matrix, which separates the living cells of the tissue.
- **4. Variable degrees of vascularity**: some types of connective tissue have a rich supply of blood vessels, other is poorly-vascularized e.g. dense CT and cartilage is avascular.

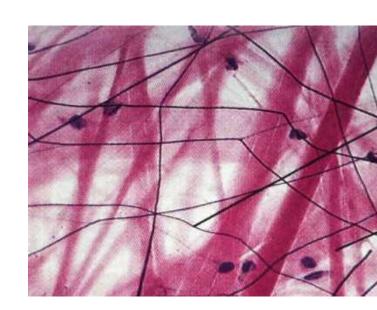

Epithelium T

- Cells: closely aggregated, of the same type and shape
- Intercellular substance: very little
- No fibers: in the ground substance
- Blood vessels: Avascular
- Origin: ectodermal, endodermal,
- Function: covering or secretion (glands)

mesodermal

Connective T

- □ Cells: few, widely separated, different types
- Intercellular substance: abundant
- Fibers: are present in the ground substance
- Blood vessels: rich
- Origin: mesodermal
- Function: support, defence and nutrition

Extracellular Matrix (ECM)

Ground Substance

It is the material that fills the spaces between the cells and contains the fibers. It is composed of:

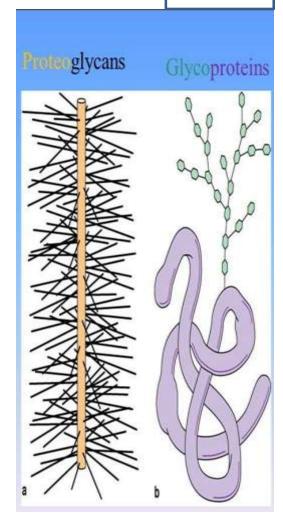

- 1. Tissue fluid: Similar to blood plasma
- 2. Adhesive glycoproteins
- 3. Proteoglycans
- 4. Glycosaminoglycans (GAG)
- 1. <u>Interstitial tissue fluid</u>: formed of plasma proteins of low molecular weight that escape through the capillary wall as a result of the hydrostatic pressure.

Edema: is an increase in the quantity of the tissue fluid due to loss of the equilibrium between the tissue fluids entering and leaving the matrix of CT.

2. Adhesive glycoproteins e.g. fibronectin and laminin.

They serve mainly as connective tissue glue that allows connective tissue cells to bind themselves to matrix elements.

Fibers

3. Proteoglycans

consist of a protein core to which glycosaminoglycans (GAGs) are attached. The strand-like GAGs are large, negatively-charged polysaccharides that extend from the core protein like the fibers of a bottle brush. GAGs are like chondroitin sulfate and keratan sulfate.

• The proteoglycans tend to form huge **proteoglycan aggregates** with hyaluronic acid that trap water, forming a substance that varies from a fluid to a viscous gel

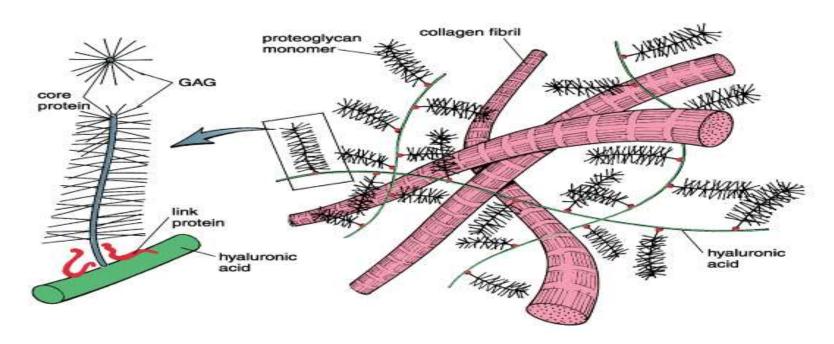

4. Glycosaminoglycans (GAG)

- ➤ linear (unbranched) polysaccharides, e.g. heparan sulfate, condroitin sulfate, keratan sulfate, hyaluronic acid
- > attract sodium & hold water
- > very hydrophilic due to abundant negative charges.
- > except for hyaluronic acid, are usually bound covalently to protein core as part of a proteoglycan

Function:

- The ground substance holds large amounts of fluid and functions as a medium through which nutrients and other dissolved substances can diffuse between the blood capillaries and the cells.
- > Its gel state serves to resist compression and to act as a lubricant.
- > It also acts as a barrier to bacterial penetration.

Some virulent bacteria can secrete the enzyme hyaluronidase that hydrolyzes the ground substance and facilitates bacterial invasion to CT.

Connective tissue fibers

- They are embedded in connective tissue matrix.
- The fibers of connective tissue provide support.
- There are three types of CT fibers:

- Collagen fibers,
- **&** Elastic fibers
- * Reticular fibers.

Collagen fibers= (white fibers)

Characters:

- -Collagen fibers are the most abundant CT fibers.
- -They are the strongest and provide **high tensile strength** (that is the ability to resist longitudinal stress). Stress test shows that collagen fibers are stronger than steel fibers of the same size.
- -In fresh state, collagen fibers have a glistening white appearance; they are therefore also called **white fibers**.

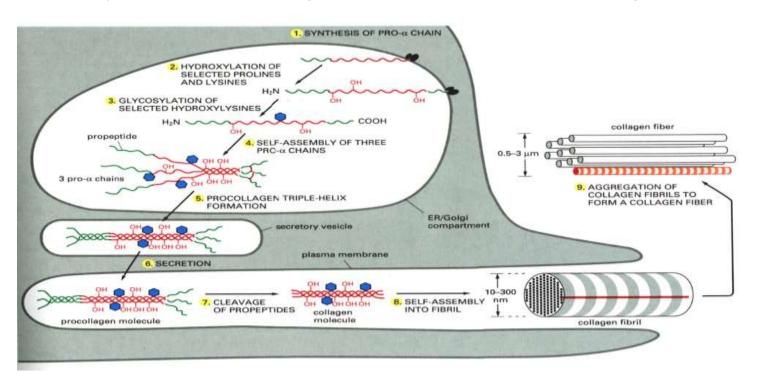

Histological features:

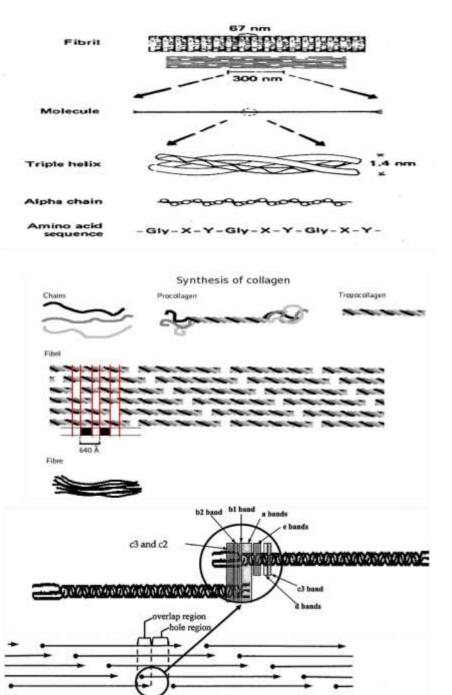

- ➤ In longitudinal section, collagen fibers appear as cylindrical structures that run in wavy bundles
- The individual fibers do not branch while the **bundles** of fibers often do.
- They stain pink with H&E

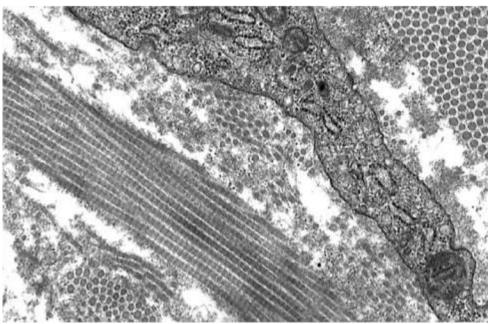

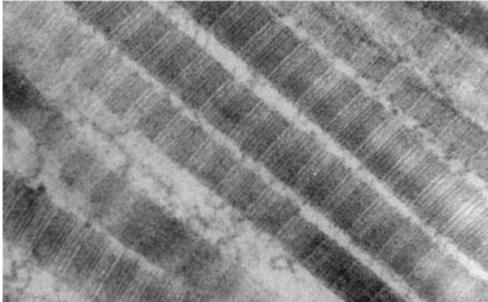

Synthesis of collagen:

- ☐ Procollagen, a precursor of collagen protein is formed inside the fibroblasts then it is released by exocytosis into the extracellular space.
- ☐ Procollagen is cleaved to form collagen molecules which assemble spontaneously into collagen fibrils.
- □ Collagen fibrils in turn are further assembled into collagen fibers which may be bundled together into the thick collagen bundles.

Collagen Fibers

E.M

Major types of Collagen Fiber

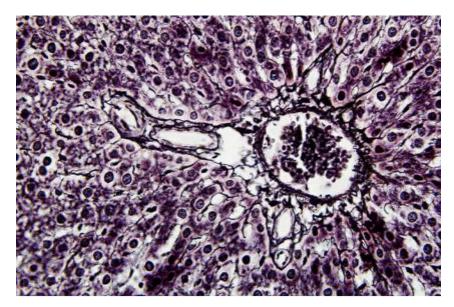

According to the chemical composition of collagen molecules Types of collagen:

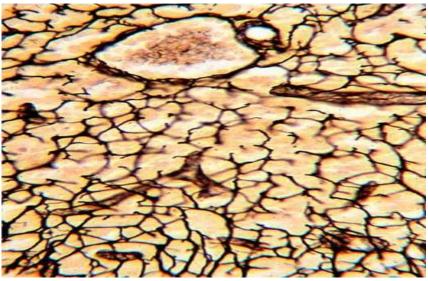

More than 20 different types of collagen fibers are known. They differ by their molecular composition, morphologic features, distribution in tissues and functions. The major types of collagen are:

- Type I collagen fibers in connective tissue proper, and in fibrocartilage and bone matrix.
- ➤ Type II collagen fibrils in cartilage matrix (hyaline and elastic).
- > Type III collagen fibers form the reticular fibers.
- ➤ Type IV,VII in basement membrane.

• •				
Collagen Type	Tissues	Function		
I (most abundant)	Skin, tendon, bone, dentin	Resistance to tension		
II	Cartilage, vitreous of eye	Resistance to pressure		
III (reticulin)	Skin, muscle, blood vessels, liver, etc.	Structural framework and stability		
IV, VII	All basement membranes	Support and filtration		

Reticular Fibers

Histological features:

- ☐Form a delicate supporting framework for highly cellular tissues (endocrine glands, lymph nodes, liver, bone marrow, spleen, smooth muscle).
- □Composed mainly of Type III collagen, with a carbohydrate moiety that reduces Ag+ to metallic sliver = argyrophilic.
- ☐ Special stain: silver stain
- ☐ Thinner than type I collagen (Type III fibrils are 30-40 nm diameter; type I fibrils are ~200 nm diameter)
- ☐ Formed by <u>reticular cells</u> (specialized fibroblasts) and vascular smooth muscle cells

Elastic Fibers yellow fibers

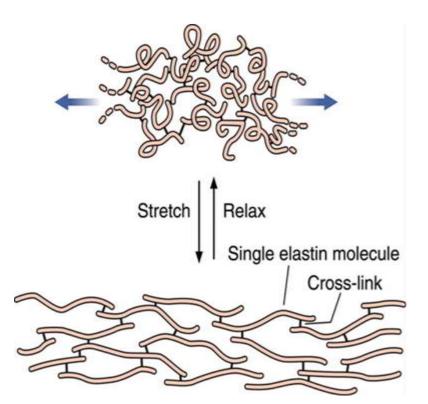

Elastic fibers: can be stretched to one and one-half times their length, but recoil to their initial length when released.

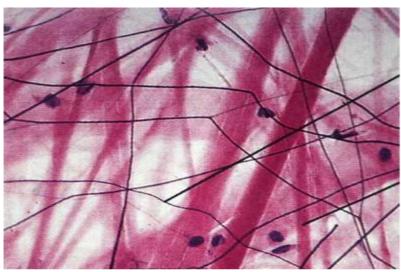

Fresh elastic fibers appear yellow and are also called **yellow fibers**.

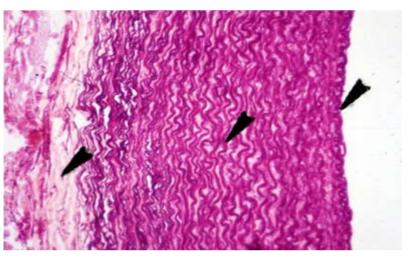

Histological features:

- These fibers contain protein, elastin that allows them to stretch and recoil like rubber bands. Because the fresh elastic fibers appear yellow, they are called **the yellow fibers**.
- They are found where greater elasticity is needed **present in large amounts in ligaments**, **lung**, **skin**, **bladder**, **and walls of blood vessels**.
- Elastic fibers may exist in **two** different forms:
- ❖Individual long and thin fibers that branch in the extracellular matrix.
- ❖In the wall of large blood vessels they form fenestrated parallel sheets
- They stain weakly with H&E.
- Special staining with **orcein stain** gives a brick-red color to elastic fibers, while staining with **V.VG stain** gives them a dark violet or black color.

Elastic fibers

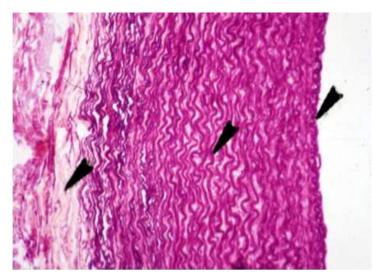

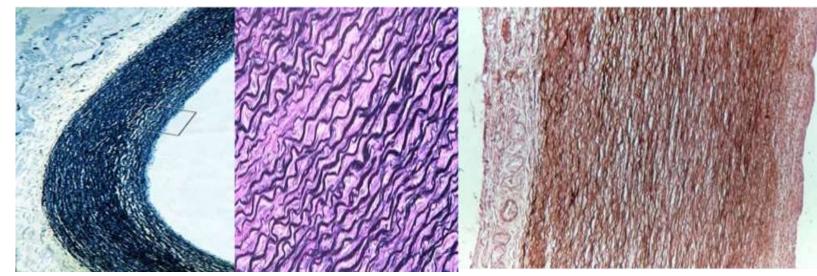

Elastic Fibers

Elastic fibers (yellow fibers): can be stretched to one and one-half times their length, but recoil to their initial length when released.

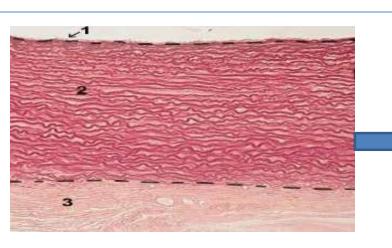

Fresh elastic fibers appear yellow and are also called yellow fibers.

Stain: H&E, Orcein, VVG

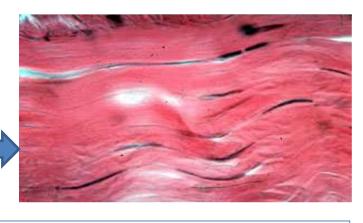

- The most numerous
- White if in great number (white fibers)
- Strong and flexible
- Fibers do not branch but bundles can do
- Formed of collagen protein
- Stain pink with eosin
- Types of Collagen Fibres

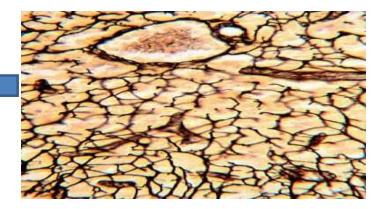

- Thin branching
- Not stained by H&E
- Stained dark brown with silver stain
- Consist of type III collagen
- Supportive function

Fibers

- Yellow if in great number (Yellow fibers)
- Elastic and stretchable
- Fibers can branch and unit
- Formed of elastin protein
- Stained weakly by H&E
- Stain brick red by orcein
- Stain dark violet with V.V.G stain.

C.T. CELLS

1

Fixed cells= resident

- ☐ stable, long-lived cell e.g.
- 1. UDMC
- 2. Fibroblast & fibrocytes
- 3. Fat cell = adipocytes
- 4. Pigment cell

Free cells = immigrating

Transient = (wandering) cells.

Originate mainly in the bone marrow and circulate in the bloodstream.

- ☐ motile, short-lived cells e.g.
- 1. Macrophages
- 2. Plasma cell
- 3. Mast cell
- 4. White blood cells= Leucocytes

Fixed cells Undifferentiated Mesenchymal Cell

Cell:

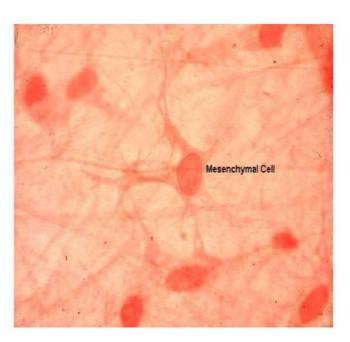

- ➤ Origin (stem cells)
- > Characters
- > Function

L.M.:

- ☐ They are stellate cells with few processes.
- ☐ They have euchromatic nuclei (active)
- ☐ with faint basophilic cytoplasm.

Function:

they are adult stem cells that can divide and differentiate into many types of CT cells.

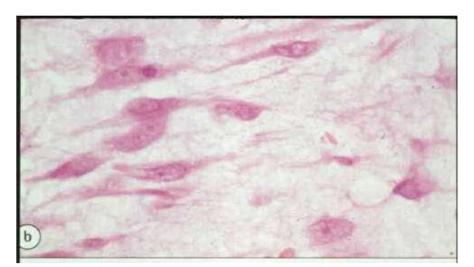

Fibroblasts 2 types

☐ Young = Fibroblasts

The most common type

- ■Origin : from UDMC
- **☐** Young active = fibroblast
- Large in size
- •Fusiform with processes
- oval central paler nucleus
- Basophilic cytoplasm = numerous rER

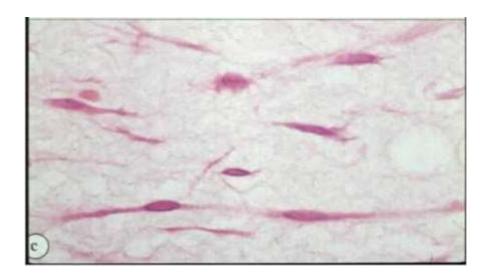

☐ Mature = fibrocytes

□ Mature = fibrocytes

mature (Fibrocytes) :inactive

- ■Small in size
- •Fusiform smaller
- oval central darker nucleus
- acidophilic cytoplasm

Fibroblasts

They are the most common cells in CT.

LM:

fibroblast is a spindle-shaped branching cell, with deeply basophilic cytoplasm and large euchromatic nucleus with prominent nucleolus.

EM:

its cytoplasm contains abundant rough endoplasmic reticulum and well-developed Golgi complex.

Function:

- Synthesize and secrete components of the ECM: fibers and ground substance.
- ☐ Synthesize growth factors.
- ☐ Rarely undergo cell division unless tissue is injured, which activates the quiescent cells.
- ☐ Play a major role in the process of wound healing and respond to an injury by proliferating and enhanced fiber formation.

Fibrocytes

- After they synthesize the matrix, they become quiescent and are called fibrocytes.
- LM:

smaller cells with fewer processes than the fibroblasts. Dark nucleus and an acidophilic cytoplasm.

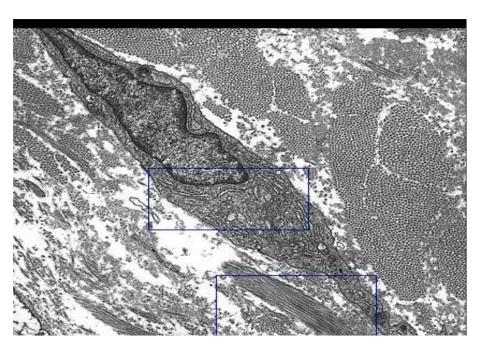

• EM:

they have fewer rER and small Golgi.

Function: maintenance of the CT matrix. However, if the matrix is injured, they can easily return to their more active state (fibroblast) to repair and regenerate the matrix.

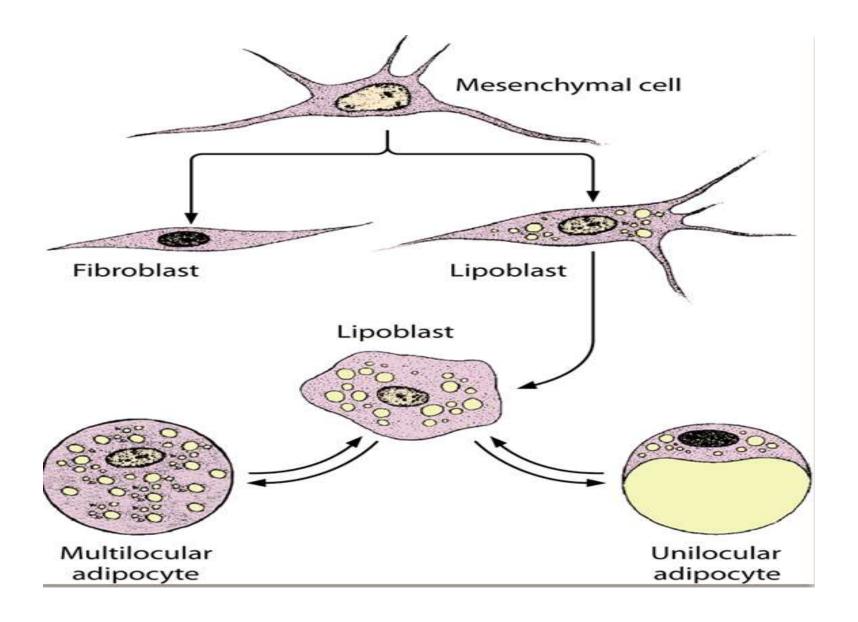

Fibroblasts E.M

Fibrocytes E.M

Fat Cell=Adipocytes= fixed cells

Adipocytes = Fat cell

Origin: UDMC

LM:

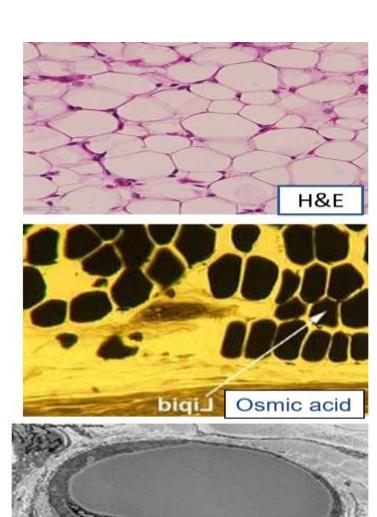

- ■large, spherical or polyhedral
- •The flattened nucleus
- •The cytoplasm only forms a very narrow rim around a large central lipid droplet.
- •Single or several lipid droplets
- •Adipocytes are long-lived cells. Their number is determined by the number of preadipocytes generated during foetal and early postnatal development.

Lipid storage/mobilisation is under:

•nervous (sympathetic), hormonal (insulin) control.

Function:

- Storage of lipid
- Production of energy
- •endocrine function they secrete the protein **leptin** which regulate appetite with feedback about the bodies fat reserves.

Histological features:

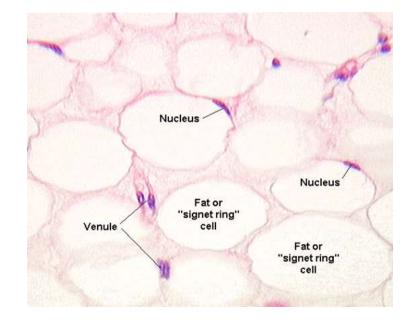

They are large cells, spherical when single or polyhedral in shape when they are closelygrouped.

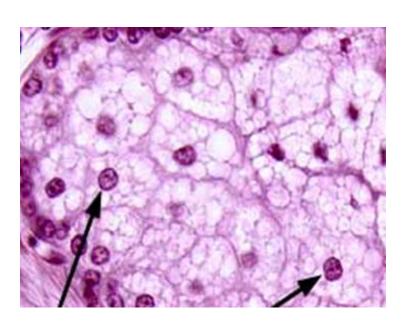

□ Unilocular adipocytes

the cytoplasm is occupied by a single large lipid droplet that pushes the cytoplasm to a thin peripheral rim with peripheral flattened nucleus giving the "signet-ring" appearance.

☐ Multilocular adipocytes are polygonal and smaller than the unilocular adipocytes.

Their cytoplasm contains a central rounded nucleus, numerous small lipid droplets and numerous mitochondria with abundant long cristae.

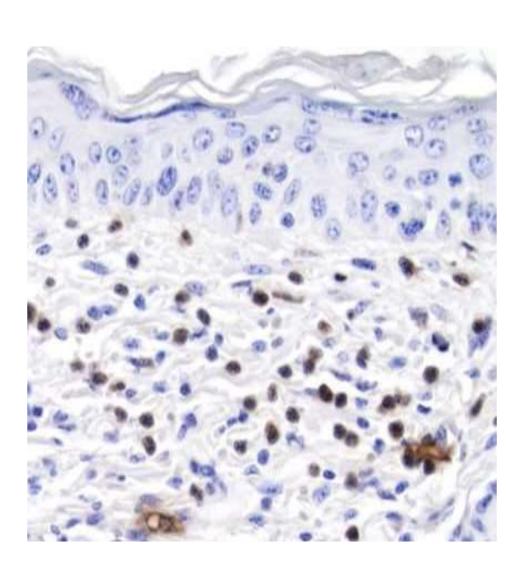

Pigment Cells= fixed cells

- •Origin :UDMC
- branched cells
- Contain pigment granules:

Melanin (melanocytes)

Function:

• gives the color of skin and iris of the eye

Free cells Mast Cells

Origin: from haemopoetic stem cell in B. M

Two types:

- Connective tissue mast cells are found in skin (dermis) and peritoneal cavity
- > mucosal mast cells are in the mucosa of the digestive and respiratory tracts.
- ☐ Contain basophilic granules by H&E
- (Metachromatic staining) By toluidine blue

when stained with toluidine blue, the granules bind the dye and change its color to red.

Histological features:

LM:

mast cell is a large CT cell. Its cytoplasm is full of basophilic granules that may obscure the nucleus. Its nucleus is rounded and central in position.

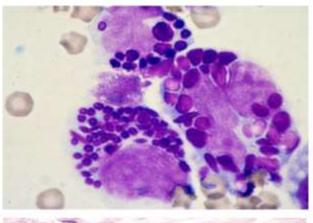

• A distinctive staining feature of mast cells is "metachromasia" which means that certain basic stains give to their granules a color other than that of the dye itself e.g. toluidine blue stain gives a purple color instead of blue, due to the chemical composition of the secretory granules.

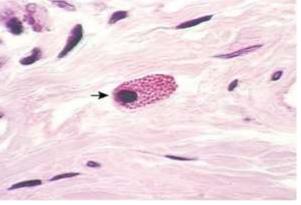

EM:

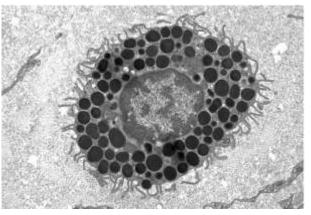

their cytoplasm contains numerous secretory granules.

Function:

they initiate allergic and local inflammatory responses by release of their granules (degranulation) which contain; the anticoagulant **heparin** and **histamine** which promotes increased vascular permeability and smooth muscles contraction.

Macrophages= Histocytes

Origin: From **blood monocytes**

Macrophages: they are derived from the monocytes that migrate from bloodstream into CT.

Histological features:

large, irregular cells with eccentric kidney-shaped nucleus.

The cytoplasm shows numerous lysosomes.

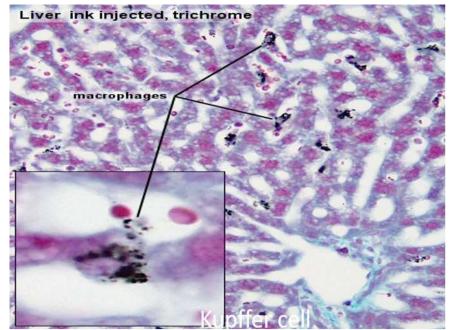

Three types:

- **Resident** :resting
- Elicited: moving to a stimulus
- Activated: active in phagcytosis:
- > pseudopodea
- Kidney shaped eccentric nucleus-
- > large number of lysosomes

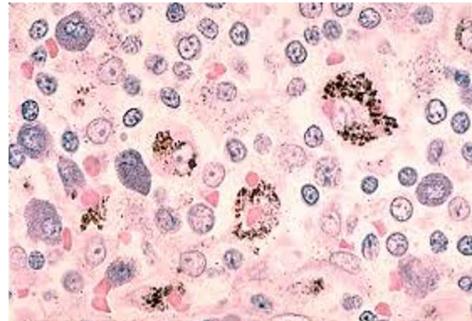

Function:

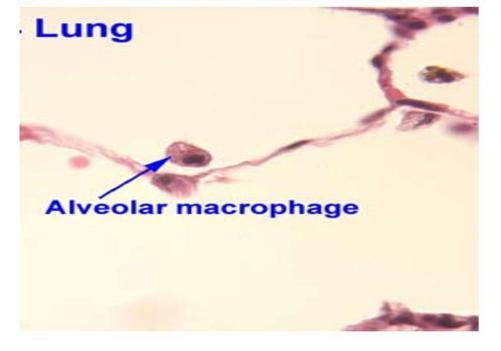

Phagocytosis, they are phagocytic cells; macrophages engulf a broad variety of foreign materials including bacteria, dead cells and dust particles.

Kupffer cell in liver

Plasma Cells

Origin: they are derived from

B lymphocytes that enter the CT.

Histological features:

LM:

they are large oval cells, with basophilic cytoplasm. The nucleus is spherical and eccentrically-placed. The chromatin of the nucleus is arranged giving the nucleus a **cart-wheel appearance**.

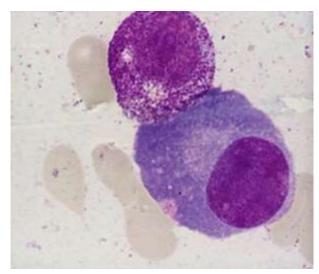

• The prominent juxtanuclear Golgi apparatus appears unstained "**negative Golgi image**" against the deeply-basophilic cytoplasm.

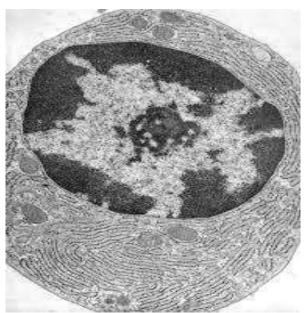

EM:

The cytoplasm shows closely-packed cisternae of rER together with large juxtanuclear Golgi complex.

Function:

they are responsible for synthesis of antibodies against bacteria and foreign proteins penetrating into the CT.

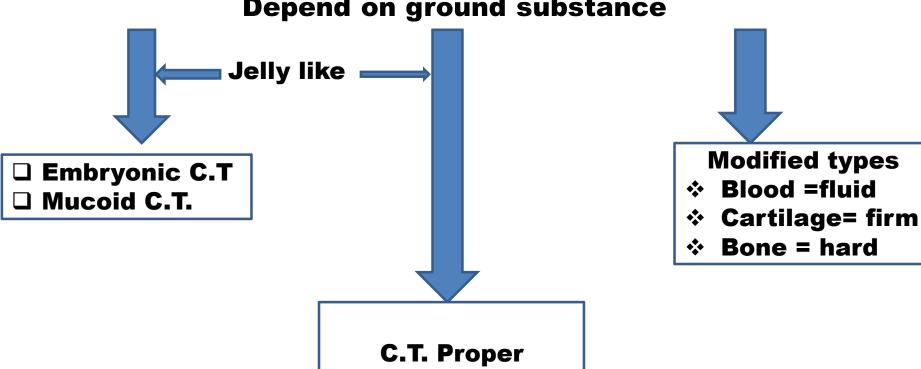

White blood cells (leukocytes)

They include neutrophils, eosinophils, basophils, monocytes and lymphocytes.

Classification of C.T.

Depend on ground substance

Loose C.T.

Dense C.T.

CLASSIFICATION OF CONNECTIVE TISSUE

•	P •	•	1		1		.1
เลอเา	ficat	non		nen		on	the
ICO DI	Hea		ut			UII	uic
				-			

- proportion of:
- > cells to fibers
- > Arrangement
- > types of fibers.
- Three categories can be defined:
- ☐ Connective tissue proper:
- it includes:
- ☐ Loose areolar connective tissue.
- ☐ Dense irregular connective tissue
- ☐ Dense regular connective tissue.
- ☐ Elastic connective tissue.
- ☐ Reticular connective tissue.
- ☐ Adipose connection tissue.

- □ Embryonic connective tissue
- it includes:
- Mesenchymal CT.
- > Mucoid CT.
- □ Specialized connective tissue:
- it includes:
- ☐ Cartilage.
- ☐ Bone.
- ☐ Blood.

Embryonic connective tissue

Mesenchymal CT

Site: it is found in embryo.

Histological structure:

it consists of:

- ➤ Undifferentiated mesenchymal cells (UMCs) with their processes come in contact with each other forming a network.
- ➤ A gel-like, amorphous ground substance.
- > Scattered reticular fibers.

Mucoid CT

Site: it is found in the umbilical cord and pulp of growing teeth.

Histological structure:

It consists of:

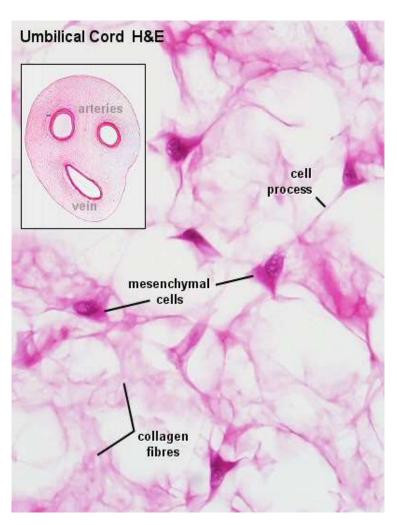

- ☐ Abundant ground substance (Wharton's jelly)
- ☐ Spindle-shaped UDMCs that are widely separated and fibroblasts.
- ☐ Unapparent fine collagen fibers that have the same refractive index as the matrix.(Type II collagen)

Mucoid C.T.= Embryonic C.T

- Mucoid connective tissue (or mucous tissue) is a type of <u>connective tissue</u> found during <u>fetal</u> development.
- It is composed mainly of ground substance with few cells & fibers
- It is most easily found as a component of Wharton's jelly.
- Cells: UDMC, Fibroblasts
- Fibers: present but not apparent collagen type II
- Ground substance : Abundant

Sites:

- Mucous connective tissue forms the <u>umbilical</u> cord.
- The <u>vitreous of the eyeball</u> is a similar tissue.

Connective tissue proper

Loose connective tissue:

relatively cell rich, soft.

It is also rich in vessels and nerves.

Loose connective tissue may occur in some special variants:

- LACT: connective tissue
- **Reticular**: connective tissue
- Adipose: tissue.

Dense CT:

- connective tissues are completely dominated by fibres.
- They are subdivided according to the arrangement of the fibres in the tissue.

Dense irregular:

connective tissue the fibres do not show a clear orientation within the tissue but instead form a densely woven threedimensional network (dermis).

Dense Regular

- 1. White fibrous C.T.
- 2. Elastic C.T.

Connective tissue proper

Loose areolar CT:

it is the most widely distributed connective tissue in the body.

It binds body parts together while allowing them to move freely over one another.

Histological structure

- All types of fibers; collagen, elastic and a small proportion of the reticular fibers.
- All types of connective tissue cells with predominance of **fibroblasts** and macrophages.
- ☐ Good amount of ground substance.
- ☐ Highly vascular

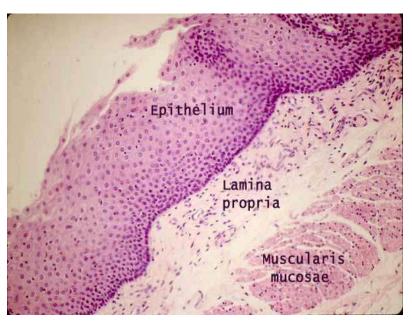

sites:

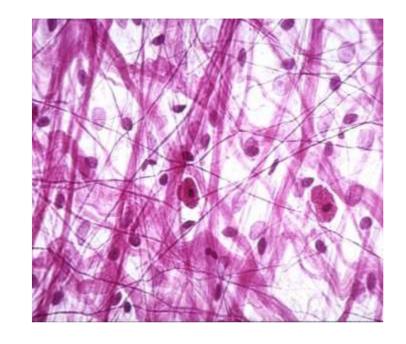

- •It is present beneath the epithelium in all mucous membranes forming the **lamina propria**.
- •It forms the **papillary layer of dermis** which attaches the skin epidermis to underlying structures.
- •It surrounds glands, small blood vessels, and nerves.

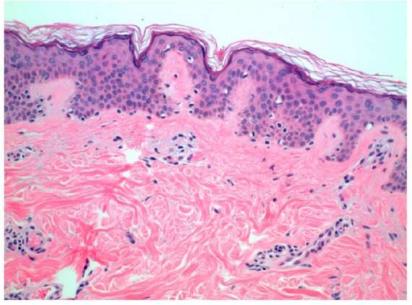

Loose Areolar C.T.

Function:

- Supports and binds other tissues (by its fibers).
- ➤ Holds body fluids and provide nutrition (by its ground substance).
- ➤ Defends against infection (by its white blood cells, plasma cells, mast cells and macrophages).

Reticular CT:

Histological structure:

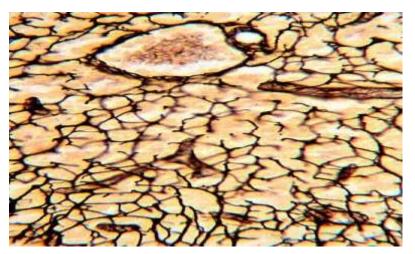

- Reticular fibers, forming a network.
- Reticular cells, these are the fibroblasts of reticular connective tissue, that synthesize the reticular fibers.

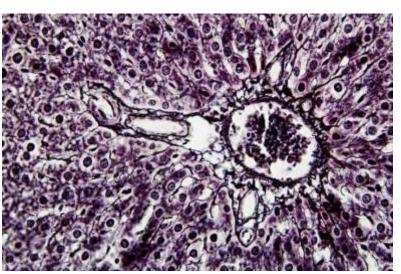

Site: reticular tissue is limited to certain sites

- ➤ Hemopoietic tissue in the bone marrow.
- Lymphoid tissue in lymph nodes and spleen.
- > In the liver.

Function

• It forms the supporting

Liver (silver stain)

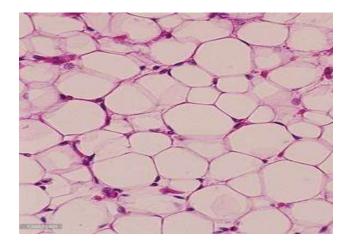

Adipose C.T.

Unilocular adipose C.T. Yellow fat

- Unilocular fat cells
- C.T. fibers: collagenous F.
- rich in blood supply
- Carotenoids

Sites:

- Subcutaneous tissue
- Around vital organs

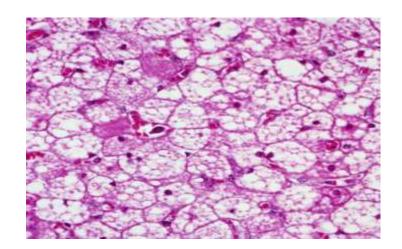

Multilocular adipose C.T. Brown fat

- Multilocular fat cells
- C.T. fibers collagenous F.
- rich in blood supply
- Many blood vessels, numerous mitochondria, cytochrome pigment

Sites:

Back & neck of newborne

Adipose C.T.

2. Lipid

- Frozen sections are used
- Sudan III → orange colour
- Sudan black → black colour
- Osmic acid → black colour

synthesismatters.blogspot.com.br

Function:

- •Storage of energy in the form of triglycerides.
- •Subcutaneous adipose tissue shapes the body.
- Pads of fatty tissue in palms and soles act as shock absorber.
- •Thermal insulation of the body; due to the poor heat conduction of adipose tissue.
- •Fixation of the vital organs as heart and kidney, thus keeping them in position.

Dense regular C.T.White Fibrous C.T.

Histological structure

- Closely-packed wavy bundles of collagen fibers running in the same direction and parallel to the direction of pull.
- Rows of fibroblasts (**tendon cells**) with flattened nuclei aligned between the collagen bundles.
- ➤ Little amount of ground substance.
- ➤ Unlike areolar CT this tissue is poorly vascularized.

Sites

- It is found in:
- Tendons, which attach muscles to bones.
- Ligaments, which bind bones together at joints.
- sclera of the eye

Function:

forms white flexible structures with great resistance to pulling forces wherever it is exerted in a single direction.

Dense Irregular CT:

Histological structure:

- Thick bundles of collagen fibers arranged irregularly (running in more than one plane).
- Little amount of ground substance with few fibroblasts.

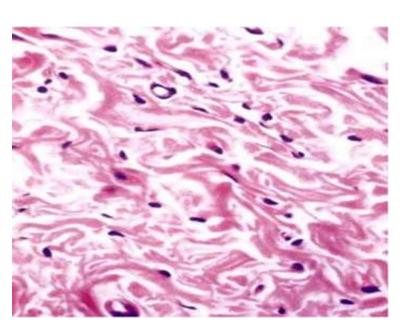

Sites:

It is found in:

- **reticular layer of dermis** of the skin.
- ☐ It forms the capsules of fibrous joints.
- ☐ It forms the capsules of body organs e.g. kidney, spleen, lymph nodes and liver.

Function

forms sheets in body areas where tension is exerted from many different directions.

Elastic C.T.

Histological structure:

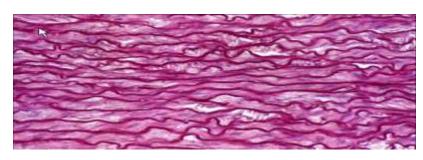

elastic fibers predominate; they run in all directions, also they may form fenestrated membranes.

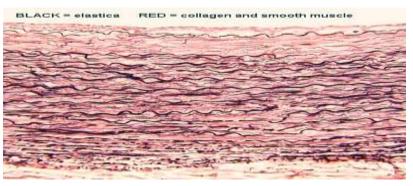

Site:

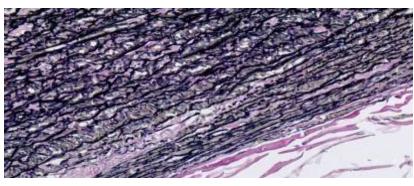

it is found in:

- ☐ Elastic laminae of arteries.
- ☐ True vocal cords.
- ☐ Few ligaments in the body are very elastic such as ligamenta flava and ligamenta nuchae connecting adjacent vertebrae.

Function: this tissue is present where flexibility and elastic recoil are needed

CONNECTIVE TISSUE

- Connective tissues are the most abundant of the primary tissues.
- The cells of the connective tissues are far apart, separated by an abundant amount of extracellular material, also called extracellular matrix

Function:

- 1. Bind together and provide mechanical support for other tissue (metabolic, defense, transport, storage)
- 2. Architectural **framework** of the body
- 3. Insulation: Fat cells or adipose tissue, is a connective tissue which not only cushions body organs but also insulates them and provides reserve energy fuel.
- 4. Nutrition
- **5. Protection:** inflammatory response
- 6. Wound repair
- 7. Transportation:
 Blood is a connective tissue and it carries and delivers oxygen and nutrient to tissues.
