

بِسْمِ اللَّهِ الرَّحْمَنِ الرَّحِيمِ

**Drugs modifying noradrenergic  
transmission (part 1):  
Catecholamines**

**By**

**Dr. Mohammad Salem Hareedy**

**2024**

⇒ Adrenalin and noradrenalin act on them.

## ADRENOCEPTORS :-

$\alpha_1$

- Vasoconstriction ... smooth muscle
- Increased peripheral resistance
- Increased blood pressure
- Mydriasis
- Increased closure of internal sphincter of the bladder

$\alpha_2$

- Inhibition of norepinephrine release
- Inhibition of acetylcholine release
- Inhibition of insulin release  
↳ ↑ blood glucose.

$\beta_1$

- Tachycardia
- Increased lipolysis
- Increased myocardial contractility
- Increased release of renin

$\beta_2$

- Vasodilation
- Decreased peripheral resistance
- Bronchodilation
- Increased muscle and liver glycogenolysis ↳ ↑ B glucose
- Increased release of glucagon
- Relaxed uterine smooth muscle ↳

### $\beta_3$ -adrenergic receptors ✓

□ Adipose tissues increasing lipolysis due to activation of triglyceride lipase.  
↳ release of free fat acid

□ Detrusor muscle of the bladder (relaxation). These  $\beta_3$  receptors are selectively stimulated by mirabegron and used for treating overactive bladder.  
↳ selective to  $\beta_3$  relaxation of bladder  
↳ due to permanently contracted bladder

1-what's the function of dopamine?

2-what's the type of selective drug?

## Peripheral dopamine receptors

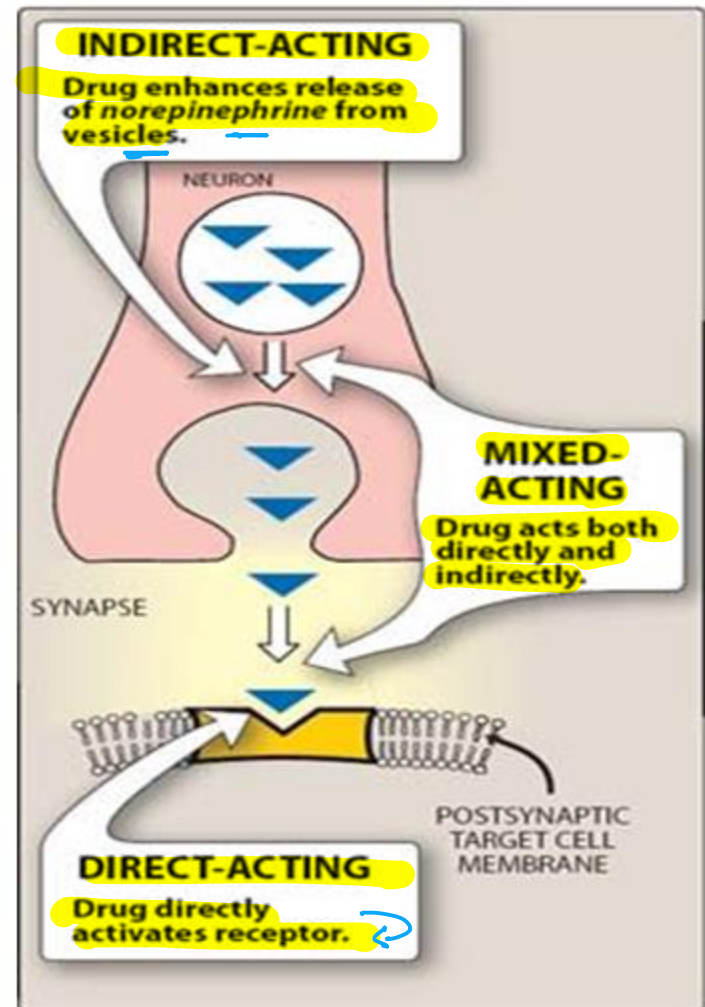

The stimulation of these receptors by Dopamine causes relaxation of renal blood vessels → increase renal blood flow.

**Fenoldopam** is a selective D1 agonist causing vasodilatation and can be used for treatment of hypertension. ✓

## Sympathomimetics (adrenergic agonists)

According to mechanism of action; sympathomimetics are classified into:

1. Direct acting ✓
2. Indirect acting ✓
3. Mixed acting ✓

1-what're the chemical classifications?

→ benzin ring + 2 OH group  
+ NH<sub>2</sub>

## Classifications of sympathomimetics According to chemical structure

### (1) Catecholamines :-

a) **Endogenous (natural)**: Epinephrine<sup>a-</sup>, Norepinephrine<sup>b-</sup> and dopamine. <sup>c-</sup>

b) **Non-endogenous or synthetic** ( $\beta$ -agonists)

- Non-selective  $\beta$ -agonist e.g., Isoproterenol.
- Selective  $\beta_1$ -agonist e.g., dobutamine.  
مشكوك في أمينه

### (2) Non-catecholamines :-

a) Selective  $\beta_2$ -agonists

b) Selective  $\alpha_1$ -agonists

c) Selective  $\alpha_2$ -agonists

d) **Indirect** acting sympathomimetics.

1- Describe the chemical structure of it?

2- why the Bioavailability = zero?

3- what's the result from changing chemical structure?

# I- Catecholamines

□ They are called catecholamines as they contain catechol ring (aromatic nucleus "benzene" and 2 OH groups). + NH<sub>2</sub>

□ All catecholamines are ineffective orally due to metabolism in GIT by MAO-A enzyme and in the liver by COMT enzyme.   
 → degraded it and oral Bioavailability = zero

## Structure-activity relationship of catecholamines and related compounds

تبدیل

Substitution on the aromatic nucleus

→ don't degraded by COMT, central activity ✓

→ No Catechol nucleus

→ Control the dynamics

Substitution on the α-carbon atom

MAO, uptake-1, NE release

Substitution on the amino group

→ Control the kinetics. → Control the affinity of binding.

sensitivity to the subunits of receptors

1- what's the mechanism of action?

endogenous

# (1) Epinephrine (EP) = Adrenaline

Mechanism of action: acts by direct stimulation (Agonist) to all types of adrenergic receptors (mainly  $\alpha$ ,  $\beta$ ) + dopamine.

# Pharmacological actions of epinephrine

1- what's the action of Ep in heart? what's the benefit of it?

2- Describe the state of epinephrine in blood vessel?

## (1) Cardiovascular effects

3- what's the result from small dose of Ep?  
4- Describe the biphasic action?  
5- Describe the Ep reversal?

### a) Heart ( $\beta_1$ )

EP is a powerful cardiac stimulant. <sup>①</sup> Tachycardia occurs, the cardiac contractility & output is increased.  $\uparrow O_2$  intake. .... used in cardiac arrest.

### b) Systemic blood vessels and blood pressure:

The blood vessels contain 2 types of receptors  $\alpha$  and  $\beta_2$ .  $\rightarrow$  response by contraction  $\rightarrow$  response by relaxation

The affinity of epinephrine is higher for  $\beta_2$ -receptors than  $\alpha$ -receptors. So, the actions of epinephrine on  $\beta_2$  receptors are more persistent. However, the number of  $\alpha$ -receptor is more than the number of  $\beta_2$ -receptors.

□ Both  $\alpha_1$  and  $\alpha_2$  stimulation causes vasoconstriction and increases in the blood pressure.

□ The stimulation of  $\beta_2$ -receptors causes vasodilatation (blood vessels of skeletal muscles) and decrease blood pressure.

**Small dose of EP** selectively activates  $\beta_2$ -receptors (higher affinity) causing vasodilation and decrease in the blood pressure (BP).

**Large dose of EP** acts on  $\beta_2$  and  $\alpha$ -receptors but as the number of  $\alpha$ -receptors is greater than  $\beta_2$ -receptors, the large dose of EP causes vasoconstriction and increase in the BP due to the  $\alpha$ -action.

At the end of the action where the concentration of EP is decreased in the blood, EP acts on  $\beta_2$ -receptors causing decrease in the BP at the end of the effect, so large dose of EP causes biphasic effect on the BP.

→ Biphasic Response.

## Epinephrine reversal:

**Large dose of EP after the administration of  $\alpha$ -blockers as prazosin acts only on  $\beta$ 2-receptors causing vasodilatation and decreases in BP.**

**Epinephrine reversal**  
( *adrenaline reversal* )

Large doses of  
Ep.

1- what's the action of  
EP in each :-

## (2) Effects on Smooth muscles

### a) GIT:

EP causes relaxation of the smooth muscles of the GIT. *No therapeutic use.*

### b) Bronchial muscles:

➤ bronchodilation ( $\beta_2$  action).

→ Treat severe asthma.

Decongested → Treat the state of dilation which cause rhinorrhea.

⊗ vasoconstriction of pulmonary blood vessels ( $\alpha$ -action), so it decreases the pulmonary congestion and bronchial secretion.

➤ ↓ the release of inflammatory mediators from mast cell ( $\beta_2$  action).

### c) Urinary muscles:

EP causes relaxation of the detrusor muscle of the urinary bladder ( $\beta_2, \beta_3$ -actions) with contraction of the sphincter, and prostate ( $\alpha_1$ -action) that may cause retention of urine.

#### d) Eye

The radial (Pupillary dilator) muscle of the iris is Contracted ( $\alpha_1$ -action) causing active mydriasis.  
⊕  
↳ decongested effect

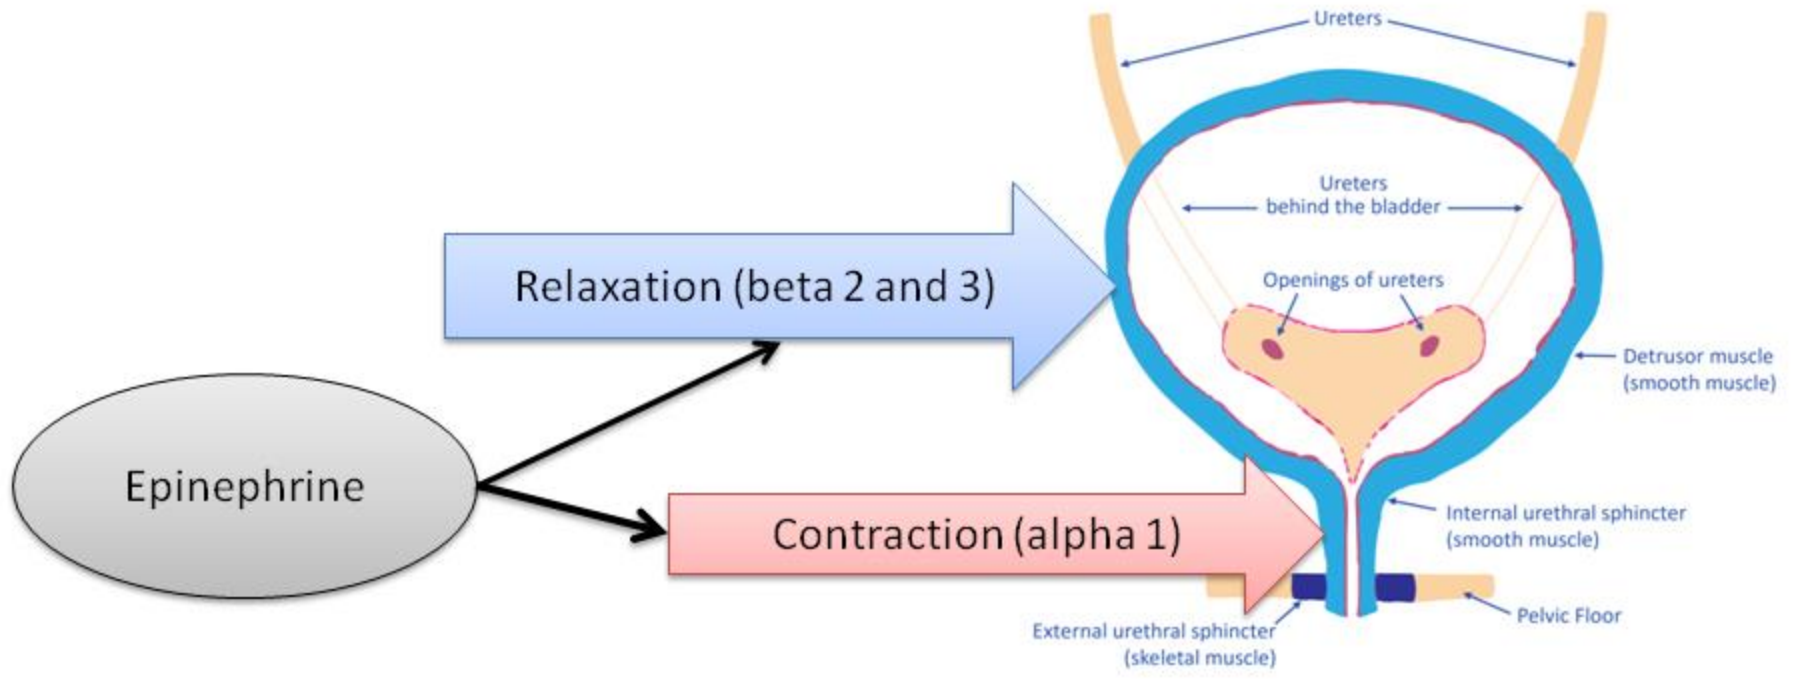

vasoconstriction of blood vessels ( $\alpha$ -action) would decreases the I.O.P due to with reduction in aqueous humor formation. It is useful in patients with wide (open) angle glaucoma.  
⇒ Vas constriction → ↓ aqueous humor  
المياه الزرقاء → ↓ IOP

#### e) Pilomotor smooth muscles:

EP causes contraction ( $\alpha_1$ -action) leading to erection of hairs (goose flesh). EP causes also increase in the sweating with pallor of skin.

#### f) Uterus:

EP causes relaxation of the pregnant uterus near term ( $\beta_2$ -action) but it causes contraction of non-pregnant uterus ( $\alpha_1$ -action). ✓

### (3) Metabolic effects <sup>?!?</sup>

a) EP  $\uparrow$  the blood glucose (hyperglycemia) mainly due to:

- $\uparrow$  glycogenolysis and gluconeogenesis (mainly  $\beta_2$ ) in liver.
- $\downarrow$  insulin secretion ( $\alpha_2$ -action).
- $\uparrow$  in the release of glucagon ( $\beta_2$ -action).

b) Increase in blood lactate due to:  $\uparrow$  lactic acid.

- $\uparrow$  glycogenolysis in the skeletal muscles.
- 

c) Increase in the free fatty acids leading to hyperlipidemia due to action on  $\beta_3$ -receptors in adipose tissue causing  $\uparrow$  lipolysis.

**Clinical note: The increased incidence of atherosclerosis and coronary artery disease that are associated with chronic stress may be partially due to the metabolic consequences of chronic sympathetic stimulation.**

1- what's the action of it in CNS?

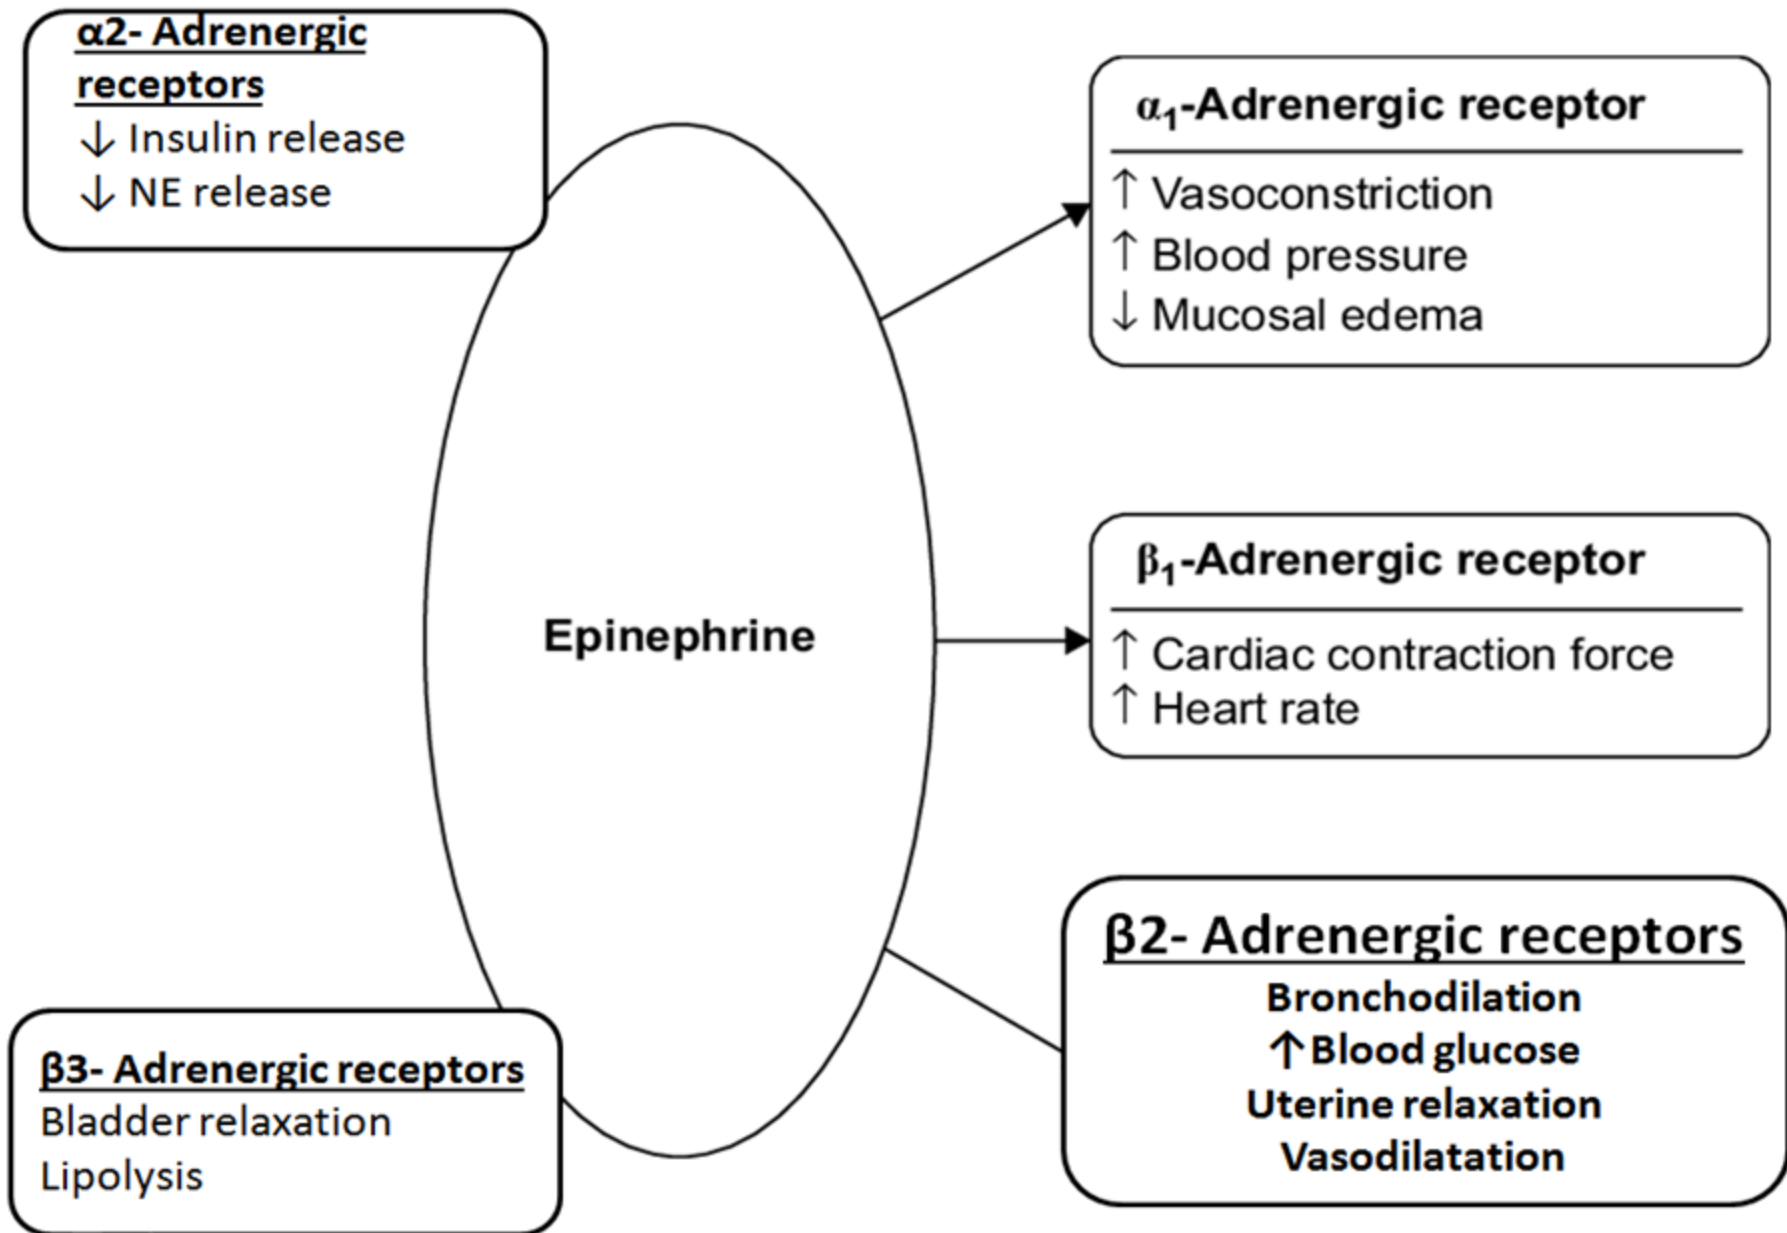

#### (4) CNS

EP is **not significantly cross the BBB**, due to catechol natures

It may cause **tremors** (secondary to cardiac and metabolic effects).

#### (5) Other effects

- It **increases** the blood coagulation by increasing the activity of factor V. Epinephrine also increases platelet aggregation (alpha 2).
- **Potent Anti-allergic effect** as it decreases the urticaria and angioneurotic edema.
- Epinephrine stimulates rennin release from the kidney (**beta 1** effect) leading to **salt and water retention and vasoconstriction**.

1- What're the rout of absorption?  
what's special about them?

2- Describe the metabolism effect?

3- Describe its excretion?

# Pharmacokinetics of Epinephrine

## 1- Absorption and routes of administration:

- It is not taken orally due to extensive first pass metabolism
- There is slow absorption after S.C. use due to its vasoconstrictor effect and absorption can be enhanced by local hot fomentation and massage.
- There is rapid absorption after I.M. use. *short duration due to large vessels of muscle*
- It can be taken by inhalation (in asthma).
- It is used intracardiac in cardiac arrest.
- It is rarely used I.V. due to its cardiovascular effects (tachycardia).

2- Metabolism: by Monoamine oxidase (MAO) and Catechol-O-methyltransferase (COMT). *phase I → oxidation, hydrolysis*

*phase II → methyl conjugation.*

3- Excretion: mainly in urine as metabolites, only 1% is excreted unchanged. *99%*

MAO = monoamine oxidase  
COMT = catechol-O-methyltransferase

# Therapeutic uses of Epinephrine

## Vascular uses:

صاغ للتوقف / Vaso constriction and stimulate platelet aggregation.

**1-Local hemostatic** to control bleeding as packs soaked in 1% EP is used to control epistaxis and bleeding after tooth extraction or via endoscopy to stop GIT bleeding. → رصف الأتف

**2-With local anesthetic** (especially for dental manipulations) as it causes vasoconstriction that decreases systemic absorption of anesthetic, increases the duration of anesthetic and decreases bleeding causing bloodless field of operation.

## Cardiac uses:

**3-Sudden cardiac arrest** due to anesthesia or hypersensitive carotid sinus, as EP intra-cardiac can be used. → in ventricle.

**4-Complete heart block** (Stokes Adams syndrome), but Isoproterenol is better as it causes less arrhythmias than EP. → without ↑ BP.

## **Allergic uses:**

**5-Acute anaphylactic shock:** S.C. or IM EP is the **drug of choice**.

It reverses hypotension, bronchospasm and laryngeal edema. Also, EP can be used in other allergic conditions (angioedema, urticaria, rash, etc....).

Ep. can decrease the degranulation of mast cells and decrease release of allergic mediators.

**6-Acute bronchial asthma:** EP is <sup>a-</sup>used S.C. or by <sup>b-</sup>inhalation as it causes bronchodilation due to  $\beta_2$ -action and decreases pulmonary congestion and edema due to  $\alpha$ -action (but it has no role in prophylaxis).

## **Ocular uses:**

7-Locally in the eye in treatment of open angle glaucoma (but now **dipivefrin**, which is a pro-drug to EP, is widely used in glaucoma).

→ prodrug .... enter the eye .... convert into EP ... ↓ Iop.

# Side effects of Epinephrine:

- 1) CVS stimulation: tachycardia, palpitation and hypertension.  
*The Role of poles in head -*
- High doses may cause arrhythmia, angina pectoris, cerebral hemorrhage and worsening of cardiac failure.
- 2) Nervousness, tremors and headache.
- 3) GIT: nausea & vomiting may occur.
- 4) Hyperglycemia and lactic acidosis. *in diabetic patients*
- 5) Pulmonary edema with toxic doses.

## Contraindications and precautions:

1-Hypertension (to avoid cerebral hemorrhage)

2-**Angina** pectoris (EP may cause myocardial infarction).

3-Congestive **heart failure**.

4-**Hyperthyroidism** (to avoid cardiac arrhythmia ).

5-**Diabetes** mellitus .

6-General anesthesia with **halothane** (to avoid arrhythmia).

7-Patients who use non-selective  $\beta$ -blockers (as EP will act only on  $\alpha$ -receptors causing marked increase in the BP that may cause **cerebral hemorrhage**).

## (2) Norepinephrine (NEP)

### NEP differs from EP in:

- It acts mainly on  $\alpha$  and  $\beta_1$ -receptors in the heart with negligable effects on ( $\beta_2$  and  $\beta_3$ ) receptors.
- It causes vasoconstriction and **increases the peripheral resistance and blood pressure** at any dose.
- in high doses; NE may elicit a reflex parasympathetic stimulation causing bradycardia in some individuals (NB: Atropine can block this reflex)
- It has weaker metabolic actions than EP.

### Therapeutic uses:

- It is used in **treatment of hypotension** and shock. *without tachycardia.*
- It is used by I.V. infusion, its action disappears after 1-2 minutes of stopping infusion, so it has a **controllable effect**.

**Side effects:** **Palpitation**, increase in the BP, headache and anxiety.

### (3) Isoproterenol (isoprenaline)

↳ Synthetic.

It is **non-selective  $\beta$ -adrenergic agonist** and acts on  $\beta_1$  and  $\beta_2$  receptors without action on  $\alpha$ -receptors.

**Therapeutic uses:** *The main drug in treatment brady cardia. and heart block.*

It is used as in emergency to increase the heart rate in patients suffering from **bradycardia and heart block**.

Now it is not used in bronchial asthma as the selective  $\beta_2$ -agonists is the best group.

**Adverse effects: Tachycardia, and hyperglycemia.**

### Beta- carbon atom

Hanging an extra hydroxyl group here tends to decrease lipid solubility, and thus decrease CNS penetration  
**ANY additional group here GREATLY increases alpha and beta receptor agonist activity.**

### Alpha- carbon atom

Any additional groups here block the action of MAO, and thus increase the half life.  
Drugs with this structure dwell longer at the synapse, and act as indirect sympathomimetics

### Amine group

A methyl group here confers alpha selectivity.  
The smaller the group, the more alpha effect there is.  
Increase of the alkyl substituent on the amine group increases the molecules preference for beta receptors instead of alpha  
The bigger the alkyl substituent, the more beta effect there is.

### The Aromatic Ring and Catechol hydroxyl groups

It all depends where you substitute the extra groups.  
You need two to have the maximum receptor affinity.

However, having two polar hydroxyl groups decreases lipid solubility and keeps you out of the brain. Having no groups like phenylethylamine results in good CNS penetration.

**Positions 3 and 5 = beta-2 selectivity in compounds with large amino substituents.**
