

ANTI-FUNGAL

1. Drugs That Target the Fungal Cell Membrane

Drug Class	Drugs	Mechanism of Action	Indications	Pharmacokinetics/Notes	Side Effects/Adverse Effects
Terbinafine	Terbinafine (superficial/systemic)	Inhibits squalene epoxidase , preventing ergosterol synthesis (fungicidal) .	Systemic (oral) and topical for dermatophytes (more effective than griseofulvin). takes 3 months to finish the course.	<ul style="list-style-type: none"> Oral active (40% bioavailability); due to 1st pass metabolism 99% bound to plasma protein deposited in nails, skin, fats and milk so contraindicated in pregnancy. half-life 200–400 hours. Metabolized in liver Excreted in the urine. 	<ul style="list-style-type: none"> GIT and taste disturbances Hepatotoxicity Headache visual disturbances.
Azoles	Ketoconazole (superficial/systemic) Itraconazole Fluconazole Posaconazole (systemic)	Inhibit fungal cytochrome P450 (14 α -demethylase), blocking ergosterol synthesis.	<ul style="list-style-type: none"> - Ketoconazole: <ul style="list-style-type: none"> Mild deep fungal infections, 2nd line to amphotericin, resistant dermatophytes to Griseofulvin and terbinafine Candida infections. - Fluconazole: <ul style="list-style-type: none"> Esophageal/oropharyngeal candidiasis Secondary prophylaxis against cryptococcal meningitis. Equivalent to amphotericin B in systemic candidiasis - Posaconazole: <ul style="list-style-type: none"> Prophylaxis during cancer chemotherapy mucormycosis. 	<ul style="list-style-type: none"> - Ketoconazole: <ul style="list-style-type: none"> oral needs acidic media plasma protein bounded metabolized in liver Do Not combine with: antacids, h2 blockers or amphotericin B. - Itraconazole/Fluconazole: <ul style="list-style-type: none"> more specific to fungal CYP450 - Fluconazole: <ul style="list-style-type: none"> Safer, less hepatotoxic - Posaconazole: <ul style="list-style-type: none"> Broadest-spectrum azole; inhibits CYP3A4. Increases cyclosporine & tacrolimus 	<ul style="list-style-type: none"> - Ketoconazole: <ul style="list-style-type: none"> Hepatotoxicity CYP450 inhibition gynecomastia adrenal suppression (corticosteroids, testosterone, female sex hormones) drug interactions astemizole& terfenadine lead to arrhythmia increase level of oral anticoagulants - Itraconazole/Fluconazole: <ul style="list-style-type: none"> Safer, fewer side effects.
Polyenes	Amphotericin B (systemic)	Binds to ergosterol , forming artificial pores in the fungal membrane, leading to leakage and cell death.	Severe deep systemic infections life-threatening meningitis	<ul style="list-style-type: none"> IV only; not absorbed orally Intrathecal for meningitis avoid infusion related side effects by slow infusion, pretreatment with antihistamine and antipyretics. To avoid nephrotoxicity, decrease the dose 	<ul style="list-style-type: none"> Infusion related: <ol style="list-style-type: none"> Fever rigors vomiting hypotension shock after IV infusion Dose related: <ul style="list-style-type: none"> nephrotoxicity convulsions.
	Nystatin (superficial)	Binds to ergosterol, forming pores in fungal membranes, causing leakage and cell death.	<ul style="list-style-type: none"> Oropharyngeal Cutaneous vaginal Candida infections (oral or topical). 	Too toxic for systemic use ; non-irritant when used topically. Used orally but not absorbed For vaginal candida both topically and orally; coz vaginal candida usually associated with GI candida ... which act as a source of reinfection	Rarely causes allergy.

2. Drugs That Target the Fungal Cell Wall

Drug Class	Drugs	Mechanism of Action	Indications	Notes	Side Effects/Adverse Effects
Echinocandins	Caspofungin, Micafungin (systemic)	Inhibit β-glucan synthesis, weakening the fungal cell wall. By blocking β 1,3 synthase enzyme which responsible for β -glucan synthesis	<ul style="list-style-type: none"> - Caspofungin: Candidiasis, invasive aspergillosis refractory to Amphotericin B. - Micafungin: Mucocutaneous candidiasis, prophylaxis of Candida infections in bone marrow transplant patients. 	IV use only.	<ul style="list-style-type: none"> GIT upset fever headache flushing (histamine release).

3. Drugs That Affect Fungal DNA/RNA or Cell Division

Drug Class	Drugs	Mechanism of Action	Indications	Pharmacokinetics/Notes	Side Effects/Adverse Effects
Antimetabolites	Flucytosine (systemic)	Cytotoxic; converted to 5-fluorouracil (5-FU) , inhibiting nucleic acid synthesis.	Cryptococcal infections (used with Amphotericin B or azoles).	Selective toxicity: mammalian cells cannot convert flucytosine into 5-FU. advantages of using Flucytosine & amphotericin B together: <ol style="list-style-type: none"> decrease resistant to amphotericin decrease amphotericin nephrotoxicity (by lowering it dose) 	<ul style="list-style-type: none"> Bone marrow suppression Hepatotoxicity hair loss.
Griseofulvin	Griseofulvin (superficial/systemic)	Fungistatic; inhibits microtubules, preventing mitosis.	<ul style="list-style-type: none"> Dermatophyte infections systemic use for resistant or widespread cases. 	Deposited in newly formed keratin (nails, hair); treatment duration: 6–12 months.	<ul style="list-style-type: none"> Teratogenic Carcinogenic Hepatotoxicity Nausea mental confusion enzyme inducer (reduces warfarin levels).
