Salivary secretion Swallowing

CRANIAL NERVES

~ 12 PAIRS

NUMBERED BASED ON ORDER THEY ARISE - EXIT THROUGH FROM NUCLEI IN THE BRAIN (EXCEPT FOR XI & XII → INVERTED)

- (S) I OLFACTORY
- (S) II OPTIC
- (M) III OCULOMOTOR
- (M) IV TROCHLEAR
- (B) V TRIGEMINAL
- (M) VI ABDUCENS
- (B) VII FACIAL
- (S) VIII VESTIBULOCOCHLEAR
- (B) IX GLOSSOPHARYNGEAL
- B) X VAGUS
- . (M) XI ACCESSORY
- (M) XII HYPOGLOSSAL

secretion (watery	• Mixed.	(t <u>hick,</u> rich in
& rich in enzy.).		mucin).
• supplied by → glossopharyngeal	• <u>Facial</u> .	• Facial. when distabled in

15 sccreeting - porchym. () flow

- Composition of saliva
- a- 99.5 % water.

b- <u>0.5 % solids</u>.

- D.3 % organic: as enzymes (amylase, Lipase, Lysozymes) and mucus. + 17/4
 - > 0.2 % inorganic:

P 4 = 6.8

- Buffers as phosphate & bicarbonate buffering systems
- ♦ Soluble calcium salts: which saturate saliva to prevent decalcification of teeth.
- Some electrolytes as Na+, Cl-, Hco3-, and K+, they act as coenzymes for salivary enzyme amylase.

Functions of saliva

swellers suy.

- 1. Facilitation of speech and deglutition.
- 2. *Cleaning (hygiene)* of the mouth by washing and antibacterial effect of lysozymes & immunoglobulin A
- 3. **Buffering function**: by bicarbonate and phosphate systems to keep the PH at about $7.0 \rightarrow$ the teeth do not loose their calcium.

Also, saliva neutralizes gastric secretion in case of gastroesophageal reflux.

- **Digestive function**:
- -Ptyalin (salivary α- amylase): digest starch to maltose in PH 6.9 so it is inhibited in the stomach.

 Trylyandes Free Pally med + 2. Lingual lyance.
- -Lingual Lipase: digest 30 % of lipids and secreted from Ebner's gland of tongue.
- 5. *Excretory function*: of lead, mercury, fluoride and some drugs as morphine and alcohol.
- 6. Facilitate taste sensation
- 7. **Regulation of water balance** (\psi in dehydration and give thirst sensation).

The Stages of salivary secretion

- > I) Salivary acini (Primary):
 - → saliva similar in composition to plasma isotonic

> II) Salivary duct (secondary):

Due modification by the duct under effect of aldosterone hormone → active reabsorption of Nat, CLo & Hco3- and active secretion of K+. So, saliva becomes hypo- tonic to plasma.

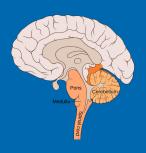

→ rish in? k

→ O2 consumption 17

→ We to Ms adive proces.

Innervation of salivary glands

A-Parasympathetic 1 secretari

It arises from superior salivatory nucleus in the pons → chorda tympani as a branch of the facial nerve→ submandibular ganglion → submandibular and sublingual glands.

Also, **Inferior salivatory nucleus in medulla oblongata** →lesser superficial petrosal nerve as a branch of **glossopharyngeal** nerve → otic ganglion → parotid gland

→ True secretion: large in volume watery, (rich in enzymes, Na+, CL-, Hco3.

Parasympathetic causes V.D of blood vessels of salivary glands # New 7

B- Sympathetic

It arises from <u>lateral horn cells</u> of the upper two thoracic segments and relay in the superior cervical sympathetic ganglia→ <u>Salivary glands</u>

- > Trophic secretion: little in volume, viscus, and rich in mucin.
- VC of blood vessels of salivary glands.

N.B

if the flow of salivary secretion increased \rightarrow little time for modification \rightarrow Na+, CL-, Hco3- & \downarrow K+ concentration as in parasympathetic stimulation.

Control of salivary secretion

Nervous only via conditioned and unconditioned reflexes.

- > [I] Unconditioned reflex
- Inborn reflex that needs no pervious learning.
- Stimuli: direct contact of food, Chewing
- Receptor: taste receptors & Receptors in GIT wall.

> Afferent

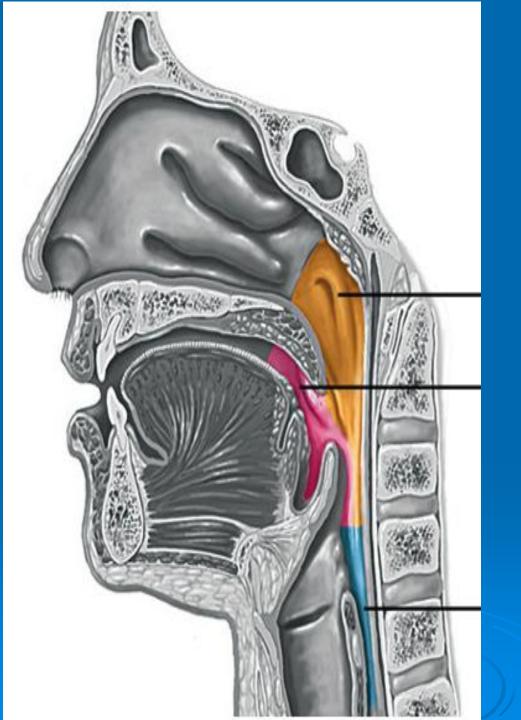

- Chorda tymparii : from ant. 2/3 of tongue.
- Glossophayngeal : from ost. 1/3 of tongue
- Ligual nerve : movement of tongue.
- Vagus nerve : from epiglottis.

- Center: superior & inferior salivatory nuclei in brain stem
- > Efferent: chordae tympani & glossopharyngeal.

[II] Conditioned reflex

- Acquired reflexes and need previous learning
- Stimuli: Sight of food.
 - Smelling of food.
 - Hearing about food.
 - -Thinking of food.
 - Receptors: special sense receptors.
 - > Afferent: optic, olfactory & auditory nerves.
 - ightharpoonup Center: to cerebral cortex ightharpoonup salivatory nuclei.
 - Efferent & response → as unconditioned reflex.

Pharynx and esophagus

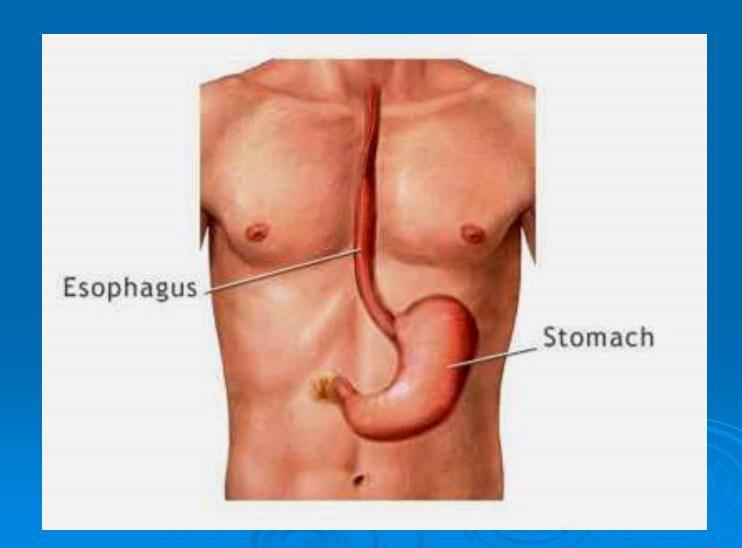

Pharynx

It is a common pathway for respiratory and digestive system and has swallowing receptor area and the primary peristalsis waves start from it. It is separated from esophagus by the upper esophageal sphincter which is normally closed.

ين الهذي وبرص بكن

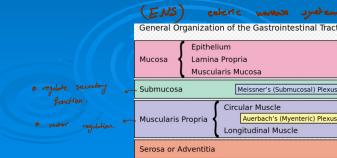

Esophagus

Esophagus

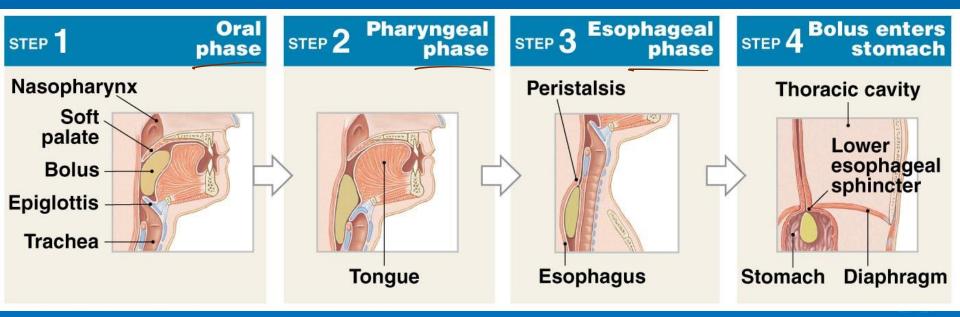

It is a muscular tube has outer longitudinal and inner circular muscle layers which are striated in the upper portion and smooth in the lower portion. So, the peristals in the upper portion depends on the value of the peristals in the upper portion depends on the vasovagal reflex, however in the lower portion it

depends on the local enteric reflex.

Swallowing (Deglutition)

- > It is the propelling of food bolus from mouth to stomach.
 - It is under control of the <u>swallowing center</u> in the <u>medulla</u>.
 - It can be divided into 3 phases:

Swallowing (Deglutition)

- > It can be divided into 3 phases:
 - Buccal phase: (voluntary)

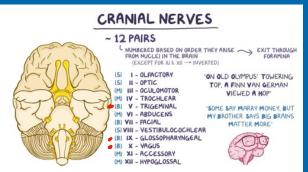

(voluntary) <u>elevation</u> and <u>retraction</u> of tongue against the hard palate propels the bolus to the pharynx.

Pharyngeal phase (involuntary)

It is very rapid (1 second), occur reflexely via:

→ Swallowing reflex

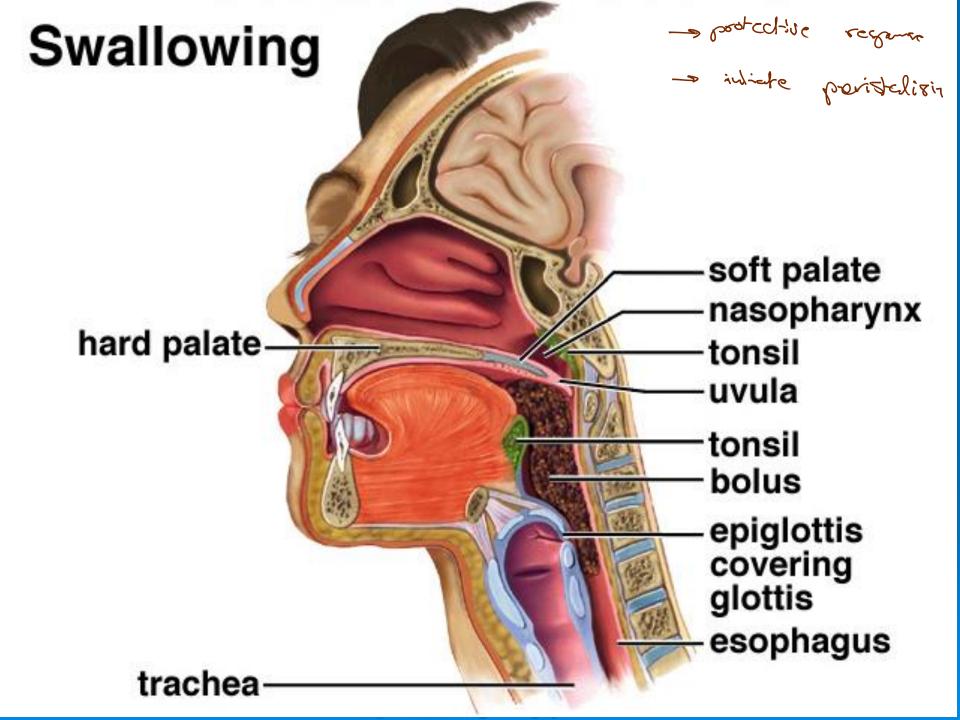

Swallowing reflex

- Receptor: in oropharynx (tonsillar pillars).
- > Afferent: 5th,9th and 10th Cranial nerves.
- Center: medulla oblongata (swallowing center).
- Efferent: motor fibers of 5th, 7th, 9th 10th and 12th cranial nerves.

- Response: Series of reflexes (Protective reflexes)
- to prevent entry of food into air passages
 - ❖ Elevation of soft palate → closure of nasal cavity.
 - ❖ Approximation of palate-pharyngeal folds → sagittal slit through which small food particles pass and prevent passage of large particles.
 - Closure of glottis (opening of larynx) by approximation of vocal words & elevation of larynx and folding of epiglottis
 - * Inhibition of breathing (swallowing apnea)

Relaxation of pharyngo-esophageal sphincter and contraction of superior pharyngeal muscle → rapid pharyngeal peristalsis → forces the food into relaxed upper esophagus.

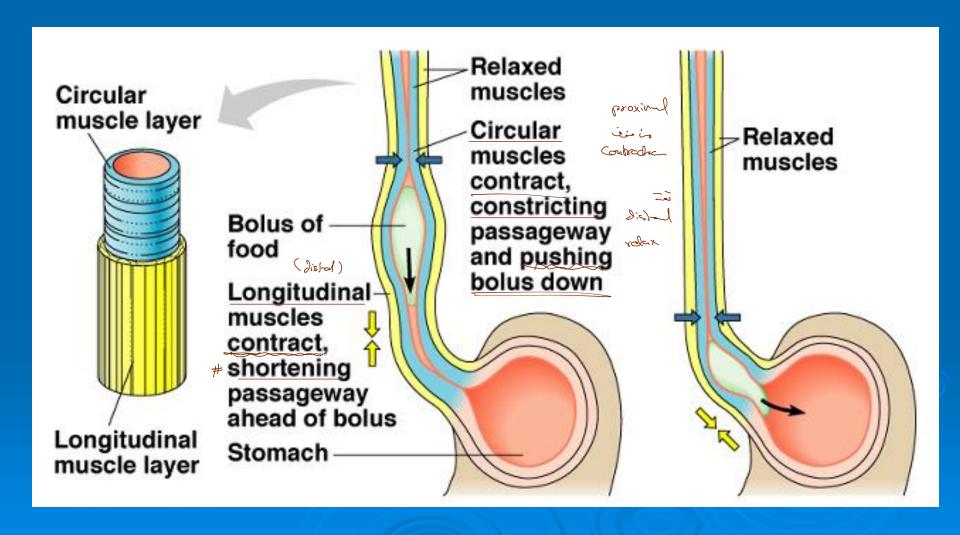

Esophageal phase (involuntary)

- Upper esophageal sphincter : (UES)
- The pharyngeo esophageal junction is normally closed by striated muscle tone to prevent entry of inspired air into stomach. During swallowing the sphincter relaxes reflexely and then reclosed after swallowing.

Traveling along the esophagus

Smooth Muscle Peristalsis Moves Food Along Alimentary Canal

Entry of food bolus into the esophagus initiate peristaltic waves of 2 types :

مج

Primary peristaltic waves:

- > They start at the upper end of esophagus.
- They are continuation of the pharyngeal peristalsis.
- ▶ It travels at the rate of 2-4 cm/sec. But gravity may increase velocity of food bolus.

5-85 - gravity 20

Secondary peristaltic waves

- Presence of bolus in the esophagus initiate peristaltic waves at site of bolus.
- These waves repeated until food bolus is driven down the stomach.
- Peristaltic movements in the upper part of esophagus is coordinated by vago – vagal reflex (striated ms.), while in lower part is coordinated by local enteric reflex.

Table summarizes the main differences between the upper & lower parts of esophagus

	Upper part	Lower part
Musculature	Striated	Smooth
Nerve Supply	Vagus nerve only	Vagus nerve + E.N.S
Movement	Rapid	Slow
Effect of bilateral Vagotomy	Complete Paralysis	⊮Secondary Peristalsis Persists

Lower esophageal sphincter (LES)

- It is called the cardiac sphincter.
- It is the lower 3-5 cm of the esophagus.
- It has high resting tone (High pressure zone) and exert a pressure 15-30 cm H₂O above intra abdominal pressure to prevent reflux of gastric content into esophagus.
- It is <u>relaxed</u> when food bolus <u>reaches</u> it with <u>some</u> delay, so this area is liable to damage or ulceration by cold, hot and spicey food.

Lower esophageal sphincter (LES)

- > Its tone is increased by : (contracted)
 - Sympathetic alpha adrenergic receptors activation.
 - Gastrin hormone (so, drugs which neutralize gastric acidity
 →↑ gastrin hormone release → contraction of the LES.

- Its tone is decreased by : (Relaxed)
 - * Inhibitory vagal effect via VIP secretion. chemical transmitters:

 Vaso active intestinal peptide. (Not acompleted interestinal)
 - Some food as fats, chocolate, alcohol & coffee.
 - II lone in Lower despheal reflux.

Achalasia

- > is failure of relaxation of lower esophageal sphincter during swallowing.
- Causes: a. Decrease the myenteric nerve plexus.
 b. High sensitivity to gastrin hormone. c. Lesions of the vagus.
- Complications: a. Mega-esophagus due to accumulation of food in the esophagus causing its dilatation. b. Increase incidence of esophageal ulcer & carcinoma. c. Recurrent pneumonia due to aspiration of esophageal contents.
- Treatment: Dilatation or surgical cardio-myotomy (removal of LES).

How gastric reflux into esophagus is prevented?

> High pressure zone sphincter. المام الديء بالمعدة، حيث تمنع رجوع

هذه العضلة تعمل مثل صمام قوي عند الطعام والعصارة المعدية إلى المريء

> بوجد جزء صغير من المرىء داخل تجويف البطن، وعندما يزداد الضغط داخل البطن (مثل أثناء السعال أو

رفع أشياء ثقيلة)، فإنه يضغط على > The intra abdominal small part of the oesoph. is هذا الجزء، مما يساعد في منع squeezed by the increased intra abdominal pressure.

The oesophagus enters the stomach in acute angle and المرىء لا يدخل المعدة بشكل act as a flap. مستقيم، بل بزاوية حادة، وهذه

الزاوية تعمل مثل صماء طبيعي أو "غطاء"، مما يحد من رجوع الحمض

Gastrin hormone increases the tone in the lower oesophagus.

Gastro esophageal reflux

- It is the return of gastric contents to esophagus due to failure of anti- reflux mechanisms as weak sphincter pressure.
- -Increases in: pregnancy, smoking, ↑ coffee, alcohol & obesity.
- Leads to: * Ulcer of lower esophagus.
- Heart burn: It is pain across the chest to neck (similar to anginal pain) due to gastric acid reflux. This pain increased at night when the patient lies flat and increased by hot drinks and alcohol.
- Stricture of cardiac sphincter.
- Barrett's esophagus due to prolonged effect on mucosa which are premalignant.
