

# Central Dogma and DNA Replication

**By:**  
**Dr/ Aya El-Hanafy**  
Associate Prof. of biochemistry &  
Molecular Biology

# Learning Outcomes

- Define **central dogma** of molecular biology
- Identify DNA replication & its general **criteria**
- Recognize the **steps** of eukaryotic DNA replication
- List **enzymes & proteins** needed for DNA replication
- Understand the meaning of end replication problem

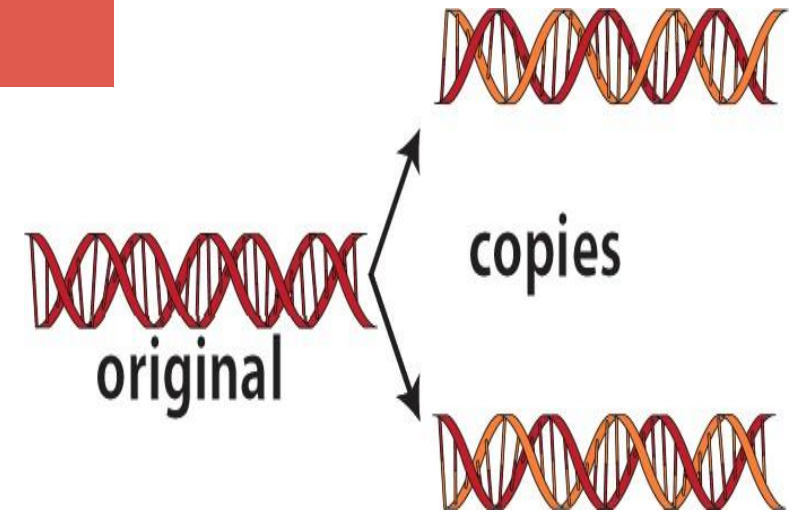

# Central Dogma of Molecular Biology

- ❑ The biological information flows from **DNA** to **RNA**, and from them to **proteins**.
- ❑ DNA in a cell must be duplicated (replicated), and passed down to daughter cells.

# DNA replication

- ❑ It is the process of making two identical DNA from the original parent DNA molecule.
- ❑ DNA has to be copied before cell division, so that the new daughter cells have the same genetic information as the parent cell.
- ❑ DNA copied during S phase (DNA synthesis) of cell cycle
- ❑ Site : in the nucleus

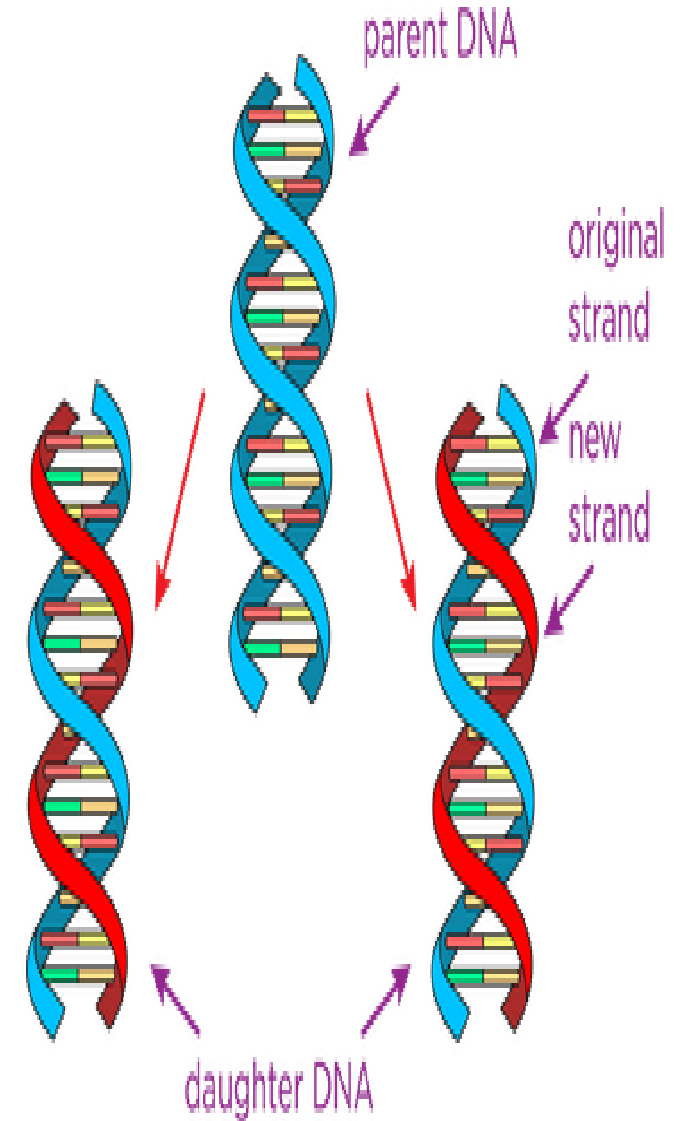

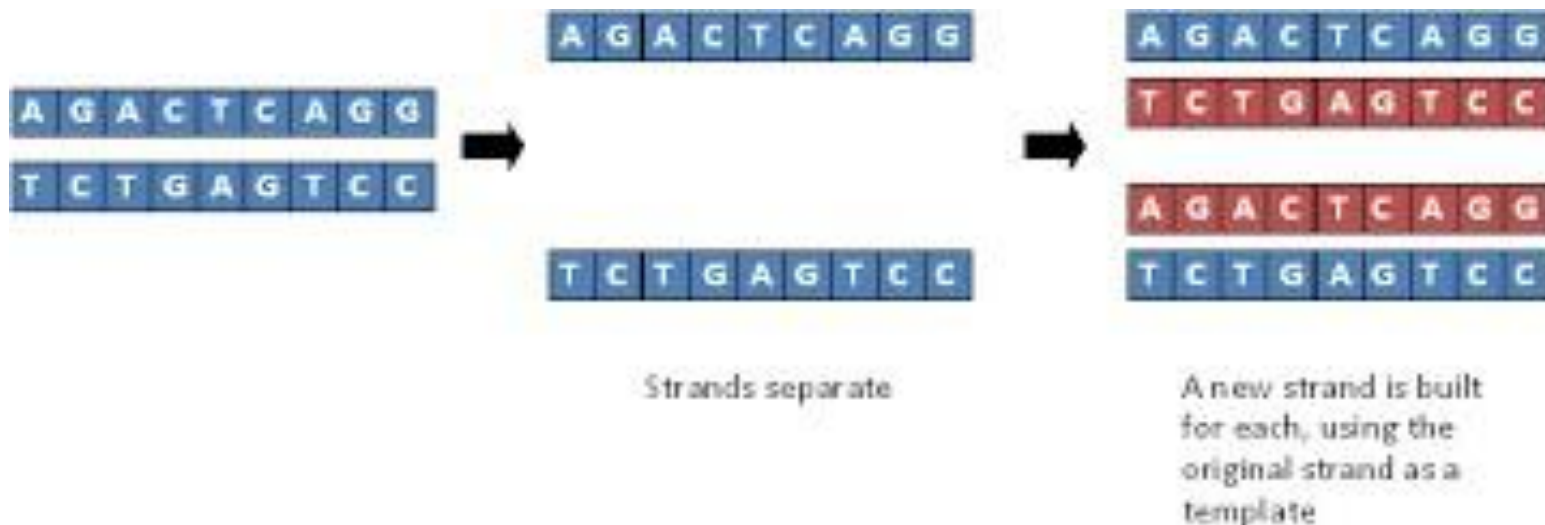

# General Criteria of DNA replication

## 1- Replication is semi-conservative.

As each daughter DNA molecule contain:

- **One old strand** (one parent strand is conserved)
- **One new strand** (from free nucleotides in nucleus)

## 2- Complementary base pairing rule is always maintained

- ❑ Adenine pairs only with Thymine [ A-T "two H bonds"]
- ❑ Cytosine pairs only with Guanine [ C-G "three H bonds"]

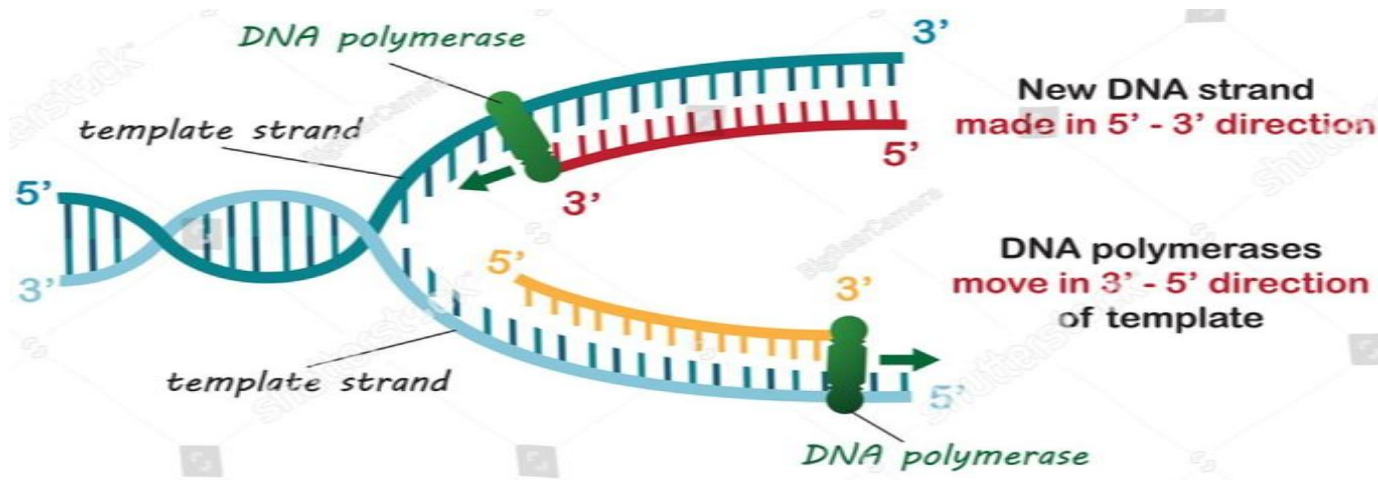

So, this means that in DNA  $A+G = T+C$

## 3- Anti-parallel strands

- ◆ One strand has a direction “5'-3'”
- ◆ complementary strand runs in opposite direction “3'-5'”

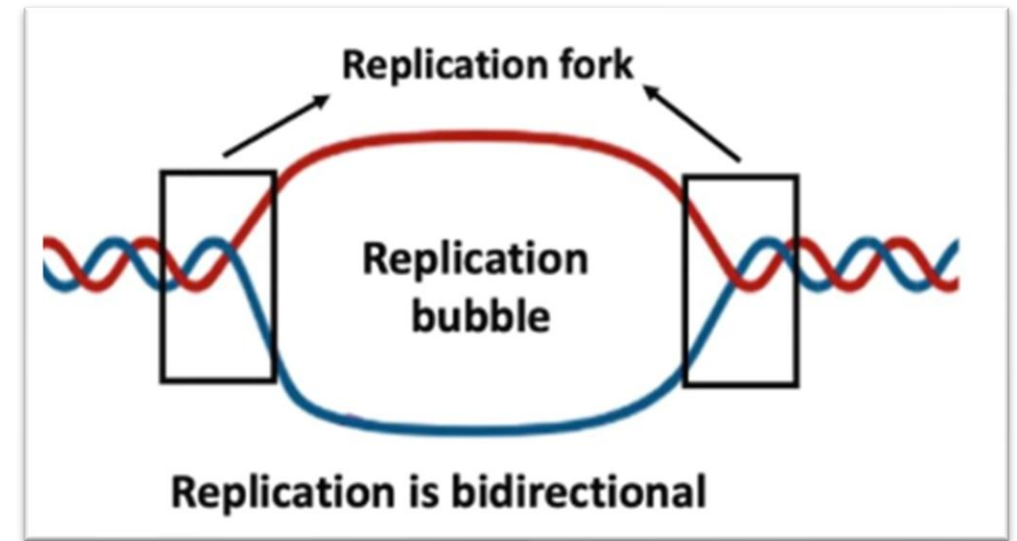

## 4- Both strands act as template

## 5- Bidirectional process

Replication proceeds in both directions

## 6- Direction of replication

Synthesis of new strand is done in 5' to 3' direction, by DNA polymerase

# The basic requirements and components of replication

- DNA template: Double stranded DNA
- Substrates: 4 Deoxyribonucleosides triphosphate  
(dA<sup>T</sup>P, dG<sup>T</sup>P, dC<sup>T</sup>P, dT<sup>T</sup>P)
- Enzymes and proteins: 

# Steps of DNA replication

1. Identification of the **origin** of replication
2. **Unwinding** of double stranded DNA and formation of **the replication fork** (replication bubbles)
3. Initiation of DNA **synthesis & elongation** in 5'-3' direction
4. **Primer removal** & ligation of newly synthesized DNA segments
5. **Proofreading** of newly synthesized DNA strands
6. **Reconstitution** of chromatin structure

## DNA REPLICATION

Overview of the eukaryotic process

# 1- Identification of the origin of replication

- Replication **starts** at points called **origins of replication, (ori)**
- These sites contain short sequence composed only of **(AT) base pairs (consensus sequence)**.
- **Specialized proteins** recognize the origin, bind to it, and **open the DNA** making its components accessible for replication

## 2- formation of replication fork

- ❑ The **DNA helicase** break the hydrogen bonds between DNA strands (It uses **ATP** molecules)

- ❑ Unwinds (separates) the 2 complementary strands.

- ❑ They form “V” shaped structure called **replication fork**.

- ❑ The two strands of DNA are kept away and separated by the **single-strand binding proteins**.

- As the 2 strands of DNA are separated, a **problem** happens called **Supercoiling** in the region of DNA ahead of the replication fork and interfere with further unwinding of the double helix.

To solve this problem:

there are a group of enzymes called **Topoisomerases**

- They have both **nuclease** (strand cutting) and **ligase** (strand resealing) activity

# 3- Initiation of DNA synthesis & elongation

- ❑ Each strand will act as a template to direct the synthesis of new daughter DNA strand.
- ❑ This occurs by **DNA polymerase enzyme**.
- ❑ **The DNA polymerases** responsible for replication are only able to **read** the parental nucleotides sequences in 3'-5' direction and **synthesize the new DNA strands only in 5'-3' direction**.
- ❑ DNA polymerases **cannot initiate** DNA synthesis by themselves, rather, it requires a **short chain of nucleotides** called a **primer** with a free OH group at 3'

# 3-Initiation of DNA synthesis & elongation

- The **primase (DNA polymerase  $\alpha$ )**: synthesizes a short stretch of RNA that are complementary and antiparallel the template DNA strands

# 3-Initiation of DNA synthesis & elongation

<u>Leading strand</u>	<u>Lagging strand:</u>
This strand copy parental strand is in the direction from Ori <b>towards</b> replication fork	This strand copy parental strand is in the direction <b>away</b> from the replication fork
Needs <u>One</u> RNA primer	Needs <u>multiple</u> primers
synthesized <u>continuously</u>	synthesized <u>discontinuously</u> in a small fragments known as Okazaki fragment
DNA polymerase $\epsilon$	DNA polymerase $\delta$

- Lagging strand is formed in the form of small fragments termed *Okazaki fragments* (each is formed of small DNA segment +RNA primer).
- Okazaki fragments are connected into one continuous strand by *ligase enzyme*.

# 3-Initiation of DNA synthesis & elongation

## DNA Polymerases :

In humans :

- **DNA Polymerase  $\alpha$**  (Primase):

Synthesize short RNA primers of Okazaki fragments

- **DNA Polymerase  $\delta$** :

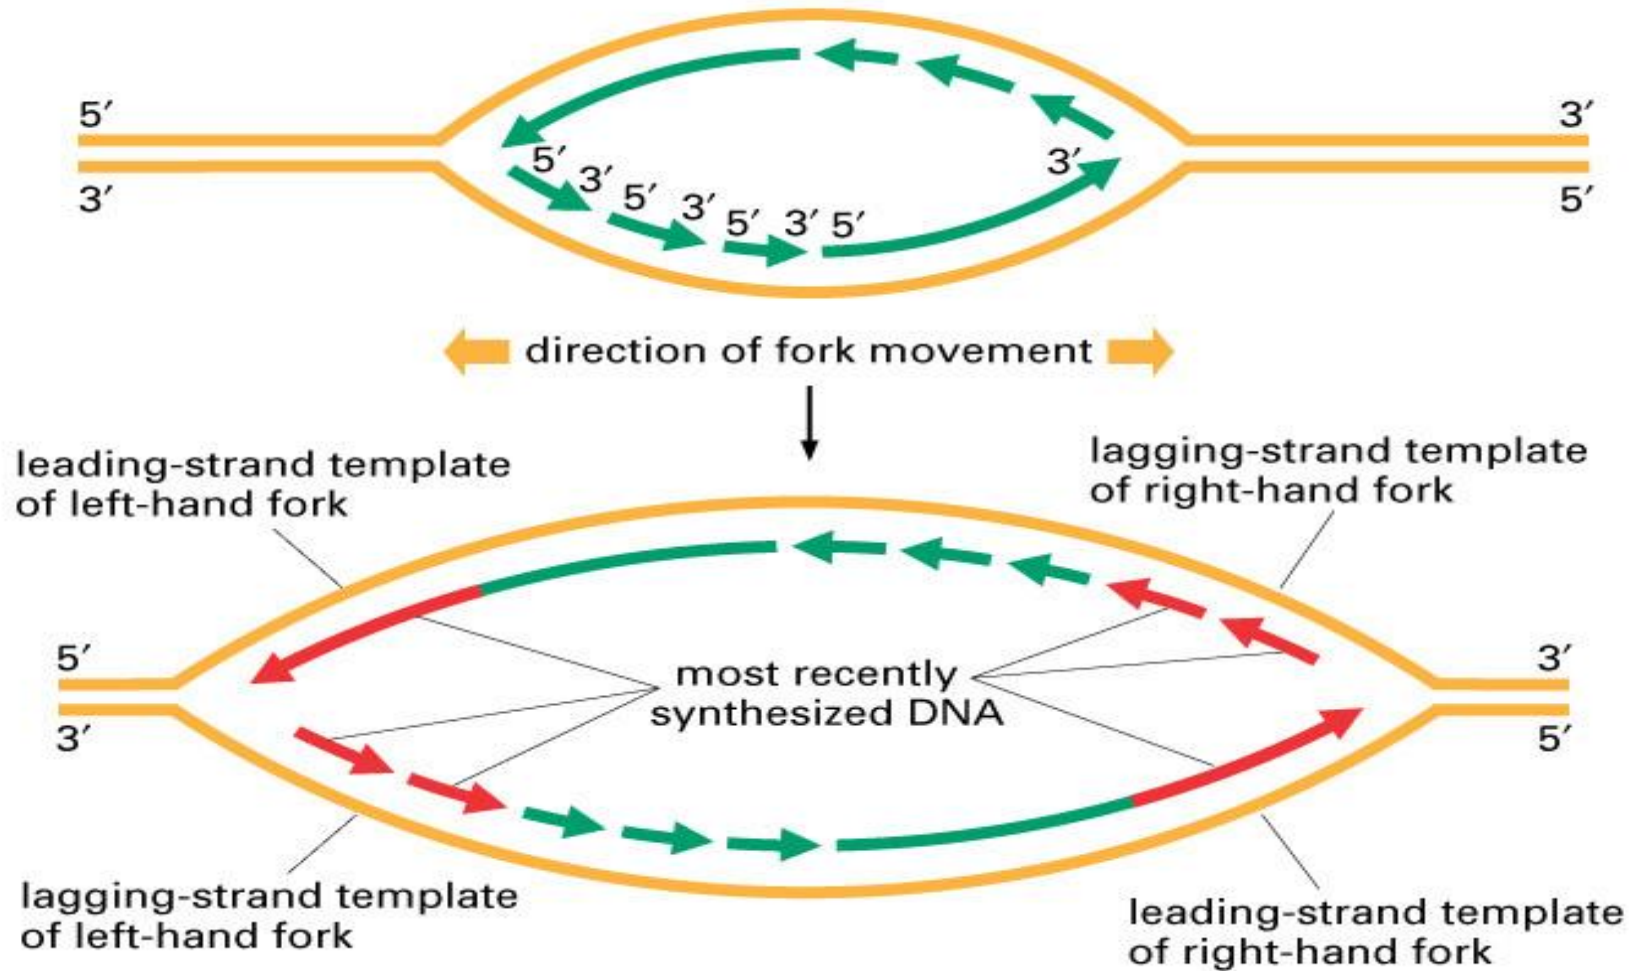

Replicate DNA lagging strand in discontinuous manner

- **DNA Polymerase  $\epsilon$** :

Replicate DNA leading strand in continuous manner

# Replication Bubble : Bidirectional replication

## 4- Primers removal and ligation of newly synthesized DNA segments

### -Excision of RNA primers:

- This occurs by Exonucleases.
- Once the primers are removed, *DNA polymerase  $\delta$*  binds to the 3' end of the preceding DNA fragment and extends the DNA over the gap.

### -Ligation of different DNA fragments:

- By DNA ligase.

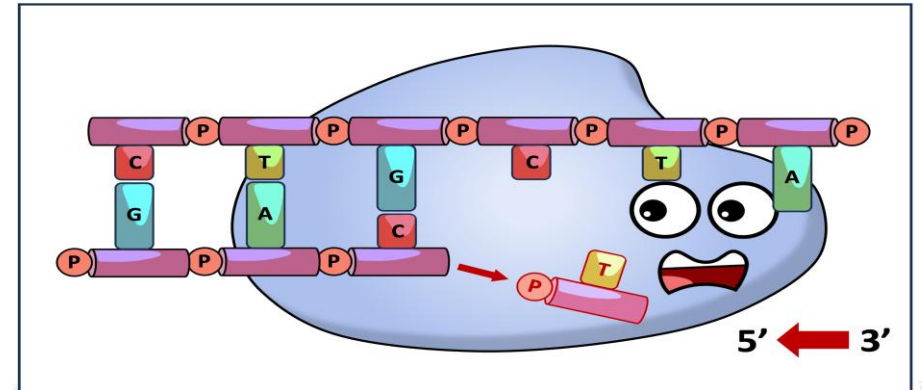

# 5- Proofreading of Newly Synthesized DNA Strands

## □ Proofreading:

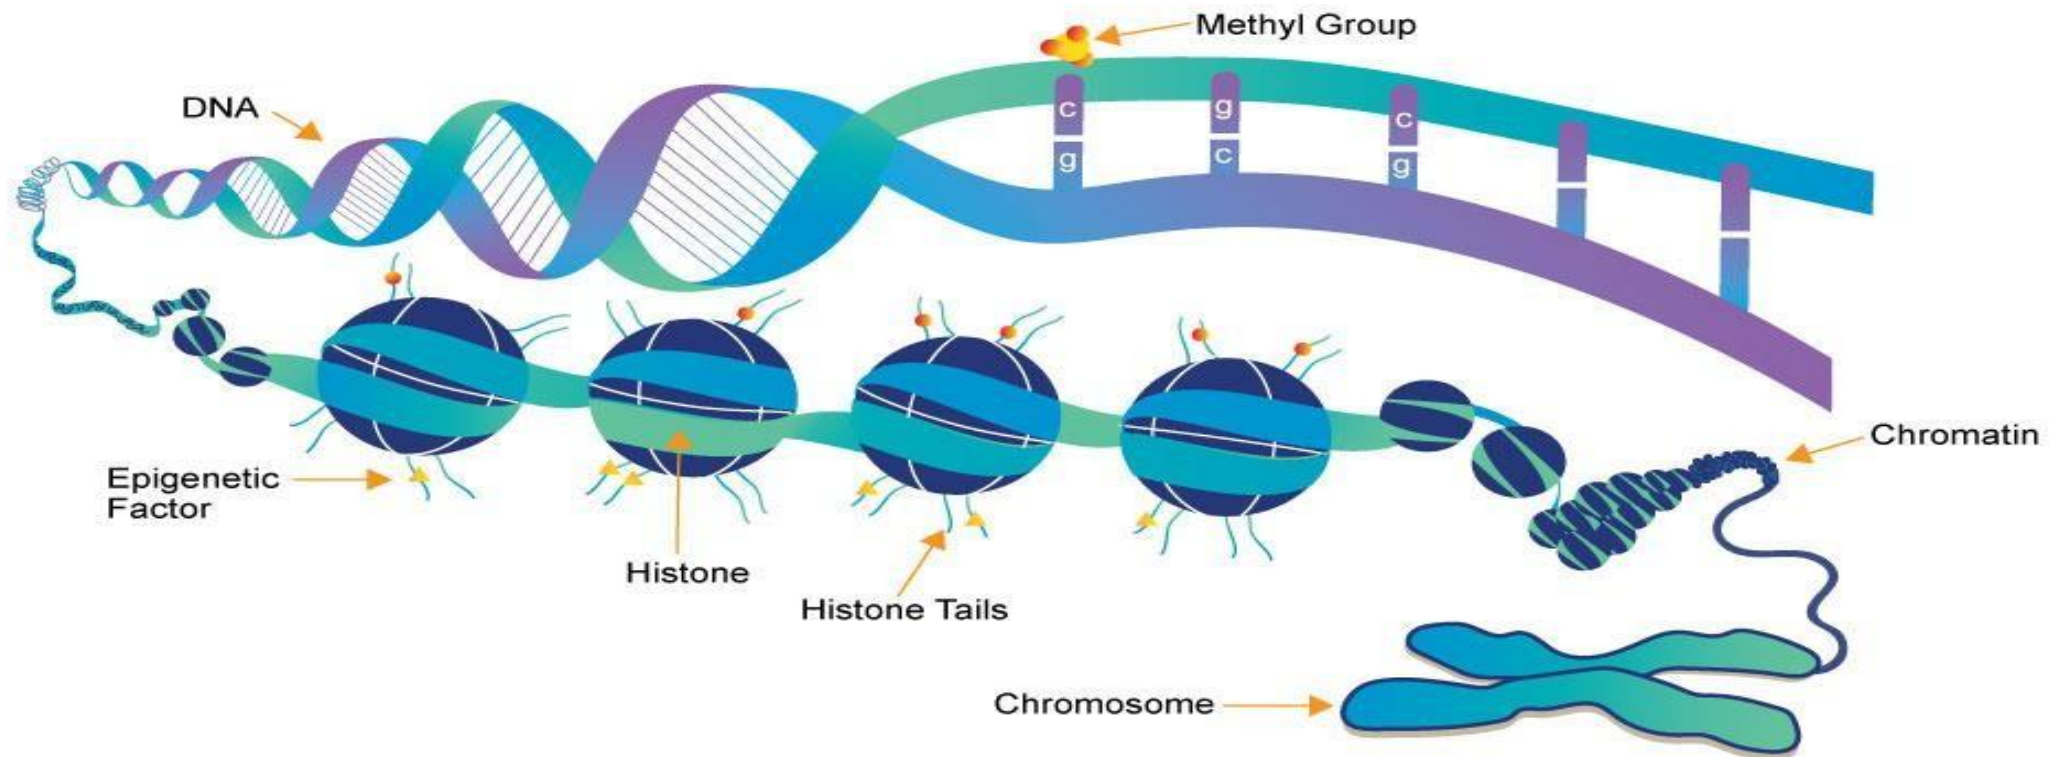

Removal of the misplaced nucleotide and replacing it with the correct nucleotide

□ As each nucleotide is added to the chain, the *DNA polymerases* ( $\delta$  and  $\epsilon$ ) check the complementary base on the template and hydrolytically remove the misplaced nucleotides

# 6- Reconstitution of chromatin structure

**Recoiling** of the parent and newly synthesized strand will result in completion of the replication process .

# Enzymes and proteins

## 1- DNA helicases

- Unwinding of dsDNA

## 2- Topoisomerase

- Relieve torsional strain results from helicase induced unwinding
- cutting and joining single strand or both strands

## 3- single stranded DNA binding protein (ssDB)

- Bind single stranded DNA and stabilize it

## 4- Primase

- RNA primer

## 5- DNA polymerase

Chief enzymes required for:

- DNA chain elongation
- DNA repair
- Proofreading

require a template and a primer (starter) and synthesize DNA in the 5' to 3' direction.

## 6- Exonuclease

- Excision of RNA primers

## 7- DNA ligase

- Join okazaki fragments

# Enzymes in DNA replication

**Helicase unwinds parental double helix**

**Binding proteins stabilize separate strands**

**Primase adds short primer to template strand**

**DNA polymerase binds nucleotides to form new strands**

**(Exonuclease) removes RNA primer and inserts the correct bases**

**Ligase joins Okazaki fragments and seals other nicks in sugar-phosphate backbone**

**+ topoisomerase**

What is the end replication problem?

Solution to  
end replication problem:  
Telomerase enzyme
