

- Dilated cardiomyopathy (DCM) is characterized by a poorly contracting dilated left ventricle with a normal or reduced left ventricular wall thickness
- It occurs more frequently in men than women and is most common between ages 20 and 60 years.
- By definition, valvular and vascular lesions (e.g., atherosclerotic coronary artery disease) that can cause cardiac dilation secondarily are absent.

DCM is the most common cause of congestive cardiac failure (CCF).

I. Dilated Cardiomyopathy

Pathogenesis

In most cases, no definite cause is identifiable, but causes can be classified as:

Genetic: in 20% to 50% of cases, either as:

autosomal dominant: mutations affecting cytoskeletal proteins or proteins that link the sarcomere to the cytoskeleton.

X-linked: mutations in dystrophin, a cell membrane protein that physically couples the intracellular cytoskeleton to the ECM.

Acquired causes such as:

Infections: e.g. coxsackievirus, adenovirus. // **Nutritional deficiency**: carnitine selenium deficiencies // **Cardiotoxins**: e.g. Adriamycin a chemotherapeutic drug // **Puerperium**: usually occur late in gestation or several weeks to months postpartum. Due to pregnancy-associated hypertension, volume overload, nutritional deficiency, gestational diabetes. // **Alcohol**:

1) direct toxic effect on the myocardium. 2) thiamine deficiency

Clinical features

The fundamental defect in DCM is ineffective contraction.

It typically manifests with signs of slowly progressive CHF, including dyspnea, easy fatigability, and poor exertional capacity.

Secondary mitral regurgitation .

abnormal cardiac rhythms.

embolism from intracardiac (mural) thrombi.

cardiac transplantation is the only definitive treatment.

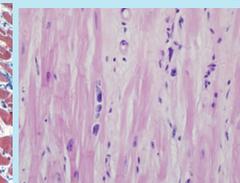

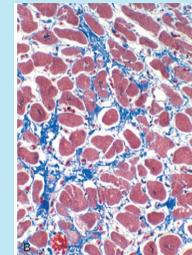

Gross Morphology

- The heart assumes a globular shape.
- ventricular chamber dilatation.
- atrial enlargement.
- Mural thrombi are often present and may be a source of thromboemboli

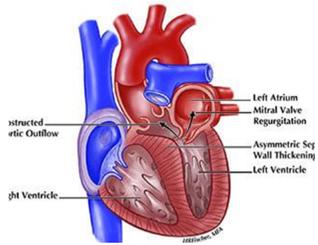

Histological features

- The characteristic histologic abnormalities in DCM are nonspecific.
- Myocytes exhibit hypertrophy with enlarged nuclei.
- interstitial and endocardial fibrosis,

2. Hypertrophic Cardiomyopathy

Hypertrophic cardiomyopathy (HCM) is defined by the presence of increased left ventricular (LV) wall thickness (in a non dilated chamber) that is not explained by abnormal loading conditions ? Typically associated with **defective diastolic** filling, and ventricular outflow obstruction. **Systolic function usually is preserved** in HCM, but the myocardium does not relax and therefore exhibits primary diastolic dysfunction

Pathogenesis

Most cases of HCM are caused by mutations (usually **autosomal dominant**) in one of the proteins that form the contractile apparatus:

1. **β -myosin heavy chain** is most frequently involved.
2. **myosin-binding protein C**.
3. **troponin T**.

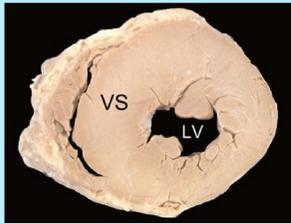

Clinical Features

HCM typically manifests during the postpubertal growth spurt. **characterized** by massive left ventricular hypertrophy associated with reduced stroke volume (due to impaired diastolic filling and overall smaller chamber size). Reduced cardiac output and a secondary **increase in pulmonary venous pressure** cause **exertional dyspnea**. A combination of massive hypertrophy, high left ventricular pressures, and compromised intramural arteries frequently **leads to myocardial ischemia** (with angina), even in the absence of concomitant CAD. **So Major clinical problems include:** atrial fibrillation with mural thrombus formation, ventricular fibrillation leading to sudden cardiac death, CHF. In almost one third of cases of sudden cardiac death in athletes younger than 35 years of age, the underlying cause is HCM.

thick-walled, heavy, and hypercontractile

Gross MORPHOLOGY

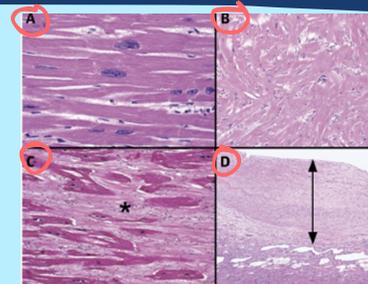

Hypertrophic cardiomyopathy is marked by massive myocardial hypertrophy without ventricular dilation.

Histological features

The characteristic histologic features in HCM are marked myocyte hypertrophy, haphazard myocyte (and myofiber) disarray, and interstitial fibrosis

- A) Myocyte hypertrophy.
- B) myocyte disarray.
- C) interstitial (pericellular-type) fibrosis (asterisk).
- D) endocardial fibrosis (double-headed arrow).

Restrictive cardiomyopathy is characterized by a primary decrease in ventricular compliance, resulting in impaired ventricular filling during diastole.

May be:

- idiopathic.
- Or associated with systemic diseases that affect the myocardium, e.g.: radiation fibrosis, amyloidosis, sarcoidosis, or products of inborn errors of metabolism.

3. Restrictive Cardiomyopathy

Commonest forms of restrictive cardiomyopathy include:

1. Cardiac amyloidosis :
 caused by the deposition of extracellular proteins (amyloid).
 can occur in the setting of:
 systemic amyloidosis (e.g., multiple myeloma).
 or restricted to the heart (e.g., senile cardiac amyloidosis).

2. Endomyocardial fibrosis :
 characterized by dense diffuse fibrosis of the ventricular endocardium and subendocardium, often involving the tricuspid and mitral valves
 is principally a disease of children and young adults.
 The fibrous tissue markedly diminishes the volume and compliance of affected chambers, resulting in a restrictive physiology.

Causes:
 nutritional deficiencies.
 inflammation related to helminthic infections with hypereosinophilia.

Functional Pattern	Left Ventricular Ejection Fraction*	Mechanisms of Heart Failure
Dilated	<40%	Impairment of contractility (systolic dysfunction)
Hypertrophic	50%–80%	Impairment of compliance (diastolic dysfunction)
Restrictive	45%–90%	Impairment of compliance (diastolic dysfunction)

*Range of normal values is approximately 50% to 65%.

Myocarditis

Myocarditis is an inflammatory disease of the myocardium caused by different infectious and noninfectious triggers.

Classified according to the cause into:

Infectious:

Viral infections, e.g.: coxsackie viruses A and B, enteroviruses, Cytomegalovirus (CMV), human immunodeficiency virus (HIV).

Noninfectious:

systemic diseases of immune origin, such as systemic lupus erythematosus and polymyositis.

Drug hypersensitivity reactions (hypersensitivity myocarditis)

Gross Morphology

- In acute myocarditis, the heart may appear normal or dilated.
- in advanced stages, the myocardium typically is flabby and pale and hemorrhagic areas.
- Mural thrombi may be present

Histological features

- edema and myocyte injury.
- interstitial inflammatory infiltrates:
 - Lymphocytic type: numerous lymphocytes.
 - hypersensitivity myocarditis: abundant eosinophils.
 - Giant cell myocarditis: containing multinucleate giant cells

Cardiac Tumors

cardiac tumors are rare. Cardiac tumors comprise primary and secondary metastatic tumors.

Primary tumors:

Primary cardiac tumors are uncommon; and usually benign.

In descending order of frequency, the most common tumors are:

Myxomas (most common).

Fibromas.

Lipomas.

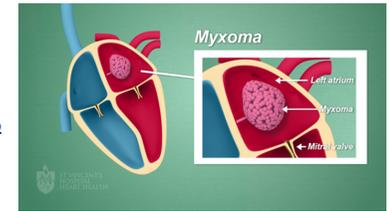

papillary fibroelastomas.

Rhabdomyomas (most frequent in infants and children, they often regress spontaneously).

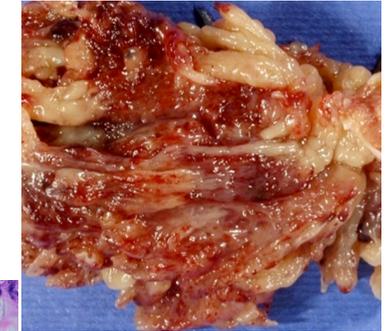

- Angiosarcomas constitute the most common primary malignant tumor of the heart.

Myxoma

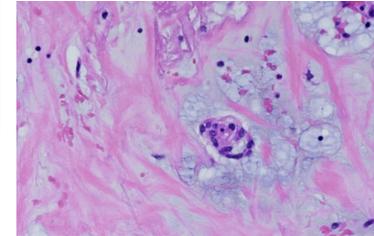

- Most common primary tumors of the heart, usually single in sporadic forms and mainly located in the left atrium.
- May cause sudden death, usually due to mitral valve obstruction.
- clinical manifestations:
 - valvular "ball-valve" obstruction.
 - embolization.
 - fever and malaise.
- Echocardiography is the diagnostic modality of choice.
- surgical resection is almost uniformly curative.

Grossly:

Microscopic:

Secondary cardiac tumors

The most frequent metastatic tumors involving the heart are: carcinomas of the lung. Carcinoma of the breast. melanomas. leukemia's and lymphomas.

Metastases can reach the heart and pericardium by: lymphatic extension. hematogenous seeding direct contiguous extension. venous extension

Carcinoid Heart Disease

- The carcinoid syndrome results from bioactive compounds such as serotonin released by carcinoid tumors (tumor arising from Neuroendocrine cells).
- Cardiac lesions typically do not occur until there is a massive hepatic metastasis since the liver normally inactivates circulating mediators before they can affect the heart.
- Classically, endocardium and valves of the right heart are primarily affected since they are the first cardiac tissues bathed by the mediators.
- The mediators elaborated by carcinoid tumors include serotonin (5-hydroxytryptamine), kallikrein, bradykinin, histamine, prostaglandins, and tachykinins.

systemic manifestations include:

- Flushing.
- diarrhea.
- Dermatitis.
- bronchoconstriction.

Direct Consequences of Tumor

Pericardial and myocardial metastases
Large vessel obstruction
Pulmonary tumor emboli

Effects of Tumor Therapy

Chemotherapy
Radiation therapy

Indirect Consequences of Tumor (Complications of Circulating Mediators)

Nonbacterial thrombotic endocarditis
Carcinoid heart disease
Pheochromocytoma-associated heart disease
Myeloma-associated amyloidosis
